· Go Under the Hood · Deep Dive Series

Runtime-level explanations of Go's core systems · what the compiler and runtime actually do under the hood. Every document includes ASCII diagrams, `runtime/` source references, performance cost tables, and production implications.

Reading Order

The documents are organized in a deliberate learning progression · from how Go stores data in memory, through its type system and concurrency model, to production debugging and enterprise patterns.

Part I · Data Structures in Depth

#	Document	What You'll Learn
01	Slices: The Three-Word Header	Slice header `{ptr, len, cap}`, `runtime.growslice`, append algorithm, backing array sharing, memory leaks
02	Maps: Buckets, Growth & the Never-Shrink Truth	`runtime.hmap`, buckets, tophash, load factor 6.5, incremental evacuation, concurrent access fatals
03	Strings: Immutability, UTF-8 & the Substring Trap	2-word header, runes vs bytes, substring memory leaks, concatenation costs, `strings.Builder`

Part II · Functions, Closures & Variables

#	Document	What You'll Learn
04	Variables: var vs := vs Explicit Type	Three declaration forms, type inference rules, `:=` redeclaration, shadowing, idiomatic conventions
05	Pointers: Auto-Deref & Auto-Address	Auto-dereference, auto-address, addressability rules, when Go silently inserts `*` and `&`
06	Closures: funcval, Capture by Reference	Block scoping, `funcval` struct, capture-by-reference, escape analysis, defer internals, Go 1.22 changes
07	Loop Variable Capture & the Fan-In Pattern	The classic loop bug, memory layout per iteration, Go 1.22 range fix, fan-in pattern line-by-line

Part III · Type System & Interfaces

#	Document	What You'll Learn
08	Interfaces: iface, eface & the Nil Trap	`iface`/`eface`, `itab` dispatch, nil trap, three guards, struct embedding & method promotion
09	The any Type: Boxing & Performance Cost	Boxing/unboxing, `convT` family, `staticuint64s`, generics vs `any`, GC shape stenciling
10	Context: The Interface Design Masterclass	4 methods, cancelCtx/timerCtx/valueCtx chain, decorator pattern, production gotchas

Part IV · Error Handling

#	Document	What You'll Learn
11	Error Chains: Wrapping, Is, As & Strategy	Sentinel errors, custom types, `%w` wrapping, `errors.Is/As` chain walk, enterprise error strategy
12	Concurrent Errors: errgroup & Recovery	WaitGroup+Mutex, channel-based collection, `errgroup.Group`, panic recovery in goroutines

Part V · Concurrency & Channels

#	Document	What You'll Learn
13	Goroutines & the GMP Scheduler	GMP model, work stealing, async preemption, syscall hand-off, network poller
14	Goroutine Stacks: Growth, Shrinking & Pointers	Contiguous stacks, 2KB·growable, pointer adjustment, stack maps, scope vs frame vs stack
15	Channels: hchan, Select & Production Patterns	`runtime.hchan`, ring buffer, `sudog` parking, select algorithm, nil channels, fan-in/out, pipelines

Part VI · Runtime & Performance

#	Document	What You'll Learn
16	Memory, GC & Escape Analysis	Stack vs heap, escape analysis rules, tri-color GC, write barrier, GOGC/GOMEMLIMIT, sync.Pool
17	Sorting: pdqsort	Pattern-defeating quicksort: insertion sort + quicksort + heapsort adaptive algorithm

Part VII · Testing & Debugging

#	Document	What You'll Learn
18	Testing Internals: go test Under the Hood	Code generation, test discovery, `_testmain.go`, white-box vs black-box, benchmarks, fuzz
19	Debugging & Profiling: pprof, trace & dlv	pprof, go tool trace, dlv, GODEBUG, deadlock detection, goroutine leak monitoring

Part VIII · Production Engineering

#	Document	What You'll Learn
20	Production Pitfalls & Enterprise Patterns	Top 15 production bugs, library comparison, project structure, graceful shutdown, Docker builds

---

How to Use These Documents

1. **Interview prep**: Read Parts I·III. These cover the most common Go interview questions at senior level.
2. **System design**: Read Parts V·VI. Understanding the scheduler and GC is critical for high-throughput services.
3. **Production readiness**: Read Parts VII·VIII. Debugging tools + pitfalls will save you in production.
4. **Quick reference**: Every doc ends with a Quick Reference Card · use them as cheat sheets.

Companion Tools

```
go build -gcflags='-m'           # escape analysis · what escapes to
heap
go build -gcflags='-m -m'        # verbose escape analysis with
reasons
go build -gcflags='-S'           # assembly output · see runtime
calls
go test -race ./...              # data race detection ·
NON-NEGOTIABLE
go test -bench=. -benchmem       # benchmark with allocation
counting
go tool pprof cpu.out            # analyze CPU profiles
go tool pprof -http=:8080 mem.out # web UI for memory profiles
go tool trace trace.out          # visual goroutine timeline
GODEBUG=gctrace=1 ./app          # GC cycle stats
GODEBUG=schedtrace=1000 ./app    # scheduler state every second
dlv debug ./cmd/server           # interactive debugger
```

Each document follows the same structure: runtime struct layout · step-by-step trace · production implications · performance cost table · quick reference card.

Deep Dive: Go Slice Internals · Header, growslice, Backing Arrays & Memory Leaks

Everything the runtime does when you create a slice, append to it, share a backing array, or accidentally leak memory through one.

Table of Contents

1 The Slice Header (`runtime.slice`)

12 Quick Reference Card

---

1. The Slice Header (`runtime.slice`)

A slice in Go is a **3-word value type** · a struct containing a pointer, a length, and a capacity. It is NOT a pointer. It is NOT a reference type. It is a **value that contains a pointer**.

```
runtime.slice (24 bytes on 64-bit)
.....................................................................
·  array unsafe.Pointer·  len   int           ·  cap   int           ·
·  (pointer to first   ·  (number of elements ·  (total elements in  ·
·   element of the     ·   accessible via     ·   backing array from ·
·   backing array)     ·   this slice header) ·   array ptr onward)  ·
.....................................................................
       8 bytes                 8 bytes                8 bytes
```

Source: `runtime/slice.go`

```
// The compiler treats slice values as this 3-word struct:
type slice struct {
    array unsafe.Pointer
    len   int
    cap   int
}
```

Why 3 Words?

```
  s := make([]int, 3, 5)
  Stack (slice header):                 Heap (backing array):
  ......................                ..............................
  · array ............................  0  ·  0  ·  0  ·  ?  ·  ?  ·
  ......................                ..............................
  · len = 3            ·                index:  0     1     2     3
 4
```

```
.....................                          ..... len .....
· cap = 5            ·                          ......... cap .........
.....................
```

- `array` · points to index 0 of the backing array. This is where the data lives.
- `len` · how many elements you can read/write via `s[i]`. Bounds-checked at runtime.
- `cap` · how many elements exist in the backing array from `array` onward. Determines whether `append` needs to allocate a new array.

Value Type With Pointer Semantics

A slice header is passed by value (copied on assignment and function calls), but the copy shares the same backing array · cheap "passing" (24-byte copy) with shared data.

```
a := []int{1, 2, 3}
b := a             // COPY of the header, SAME backing array
b[0] = 99          // mutates the shared backing array
fmt.Println(a[0])  // 99 · a sees the mutation!

  After b := a:
  a: ............                          ...................
     · array ........................     ·  1  ·  2  ·  3  ·
     · len = 3  ·                    .......     .     .     .
     · cap = 3  ·                    .     ...................
     ............                    .
  b: ............                    .
     · array ........................
     · len = 3  ·
     · cap = 3  ·
     ............
```

---

2. Arrays vs Slices · What Actually Differs

Arrays: Value Types Where Size Is Part of the Type

```
var a [5]int        // type is [5]int · the 5 is part of the type
var b [3]int        // type is [3]int · DIFFERENT type from [5]int
// a = b            // compile error: cannot use [3]int as [5]int
```

An array is a **contiguous block of memory** · no header, no indirection. The entire array IS the value. Size = `N × sizeof(T)`.

Assignment copies ALL data

```
a := [5]int{10, 20, 30, 40, 50}
b := a            // copies ALL 40 bytes · deep copy, completely
independent
b[0] = 99
fmt.Println(a[0]) // 10 · a is unchanged
```

How `s := arr[1:3]` Creates a Slice Header

```
arr := [5]int{10, 20, 30, 40, 50}
s := arr[1:3]

  arr (40 bytes on stack):
  ...............................
  · 10  · 20  · 30  · 40  · 50  ·
  ...............................
  index: 0 ·  1     2     3     4
           ·
  s (slice header · 24 bytes):
  ..................
  · array = &arr[1]···· points to index 1
  · len = 2        ·    (high - low = 3 - 1)
  · cap = 4        ·    (len(arr) - low = 5 - 1)
  ..................
  s[0] == arr[1] == 20,  s[1] == arr[2] == 30
```

Side-by-Side Comparison

```
..............................................................
· Feature          · Array              · Slice                 ·
..............................................................
· Type identity    · [N]T (N in type)   · []T (size not in type)·
· Memory size      · N × sizeof(T)      · 24B header + backing  ·
· Assignment       · Deep copy all data · Shallow (header only) ·
· Func arg pass    · Copies all data    · Copies 24B header     ·
· Can resize?      · No                 · Yes (append)          ·
· Comparable (==)? · Yes (element-wise) · No (use slices.Equal) ·
· Can be map key?  · Yes                · No                    ·
..............................................................
```

---

3. `make()` Under the Hood

```
s := make([]int, 3, 5)
```

What the Compiler Generates

The compiler translates `make([]T, len, cap)` into `runtime.makeslice()`:

Source: `runtime/slice.go`

```
func makeslice(et *_type, len, cap int) unsafe.Pointer {
    mem, overflow := math.MulUintptr(et.Size_, uintptr(cap))
    if overflow || mem > maxAlloc || len < 0 || len > cap {
        panicmakeslicecap()
    }
    return mallocgc(mem, et, true)  // allocate cap × sizeof(T)
bytes, zeroed
}
```

The Allocation Split: Header on Stack, Backing Array on Heap

```
  s := make([]int, 3, 5)
  Stack:                                Heap (mallocgc(40 bytes,
zeroed)):
  ......................                ...............................
  · array = 0xc000... ...................  0  ·  0  ·  0  ·  0  ·  0  ·
  · len   = 3          ·                ...............................
  · cap   = 5          ·
  ......................
```

`makeslice` returns `unsafe.Pointer` to the backing array. The compiler constructs the 24-byte header on the caller's stack.

Escape Analysis: When Does the Header Escape?

The slice header stays on the stack UNLESS it escapes:

```
func local() {
    s := make([]int, 0, 100)  // header: stack, backing array: heap
    s = append(s, 1, 2, 3)
    fmt.Println(len(s))
}
func leaks() []int {
    s := make([]int, 0, 100)  // header AND backing array: both on
heap
    return s                   // slice header escapes
}
```

Verify with:

```
go build -gcflags='-m' ./...
# make([]int, 0, 100) escapes to heap     · backing array
# s escapes to heap                        · header (only when
returned)
```

If the compiler can prove the backing array doesn't escape AND the size is small (known at compile time), it MAY stack-allocate the backing array too. Check with `-gcflags='-m'`.

---

4. Append Internals ·`runtime.growslice()`

`append` is the most misunderstood slice operation. Let's trace every path.

```
s = append(s, elem)
```

Critical Insight: `append` Returns a NEW Slice Header

`append` **always** returns a new slice header. You **must** reassign:

```
s = append(s, 42)   // · reassign
append(s, 42)        // · BUG · return value discarded
```

Case A: `len < cap` · No Growth Needed

```
s := make([]int, 2, 5)
```

```
s[0], s[1] = 10, 20
s = append(s, 30)   // len(2) < cap(5) · just write s[2]=30, len=3.
Same backing array.
```

Case B: `len == cap` · Growth Required

```
s := []int{10, 20, 30}   // len=3, cap=3
s = append(s, 40)         // len == cap · must grow!
```

The compiler calls `runtime.growslice()`:

```
  1. append detects: len(s) == cap(s) · no room
  2. Calls: runtime.growslice(typeof(int), old_slice, newLen=4)
  3. growslice computes new capacity (see growth algorithm below)
  4. Allocates NEW backing array via mallocgc(newCap × sizeof(T))
  5. Copies old data · new array via memmove
  6. Writes new element at position old_len
  7. Returns NEW slice header: {new_array_ptr, newLen, newCap}

  BEFORE (len=3, cap=3):          AFTER growslice (len=4, cap=6):
  ...................            ....................................
  · 10  · 20  · 30  ·  (GC'd)   · 10  · 20  · 30  · 40  ·  0  ·  0  ·
  ...................            ....................................
                                                            ·new   ·cap=6
```

The Growth Algorithm (Go 1.18+)

Source: `runtime/slice.go` ·`nextslicecap()` (changed in CL 347823)

```
  if newLen > 2×oldCap     · return newLen        (caller needs more
than 2x)
  if oldCap < 256          · return 2×oldCap      (small: double)
  else                     · oldCap += (oldCap + 768) / 4  (·1.25x +
192)
                              repeat until >= newLen

  Growth examples:  0·1  1·2  4·8  128·256  256·512  512·832  1024·~1472
  After nextslicecap, runtime rounds up to nearest memory allocator
size class
  (runtime/malloc.go · roundupsize(), ~70 classes from 8B to 32KB).

s := make([]int, 0)
for i := 0; i < 5; i++ {
    s = append(s, i)
    fmt.Printf("len=%d cap=%d\n", len(s), cap(s))
}
// Actual caps: 1, 2, 4, 4, 8 · rounded up to size class boundaries
```

Append Cost Analysis: Two Paths, Vastly Different Costs

A common misconception is that `append` is always expensive. It's not. `append` has **two completely different execution paths**:

```
                          append(s, elem)
```

```
                    .
             .............
             · len < cap? ·
             .............
            yes/         \no
            .             .
.................  ......................................
· FAST PATH     ·  · SLOW PATH (growslice)              ·
· ~2-5ns        ·  · ~100-500ns+                        ·
·               ·  ·                                    ·
· 1. Write elem ·  · 1. Compute new capacity            ·
·    at s[len]  ·  · 2. mallocgc: allocate NEW array    ·
· 2. len++      ·  · 3. memmove: copy all old elements  ·
· 3. Done       ·  · 4. Write new element               ·
·               ·  · 5. Return new slice header         ·
· No allocation ·  · 6. Old array · garbage collector   ·
· No copy       ·  ·                                    ·
· No GC work    ·  · Allocation + copy + GC pressure    ·
.................  ......................................
```

Fast path (len < cap): Nearly free. Just writes to the next slot in the already-allocated backing array and increments `len`. No allocation, no copy, no GC involvement. This is comparable to `s[i] = elem` in cost.

Slow path (len == cap): Expensive. Allocates an entirely new backing array, copies every existing element via `memmove`, writes the new element, and leaves the old array for GC to collect. The cost grows with slice size · copying 1M elements is far more expensive than copying 10.

The Practical Lesson: Pre-Allocate to Stay on the Fast Path

```
// · Starts at cap=0 · triggers growslice repeatedly
// For 1000 elements: ~10 growslice calls, ~10 dead arrays for GC
results := []int{}
for i := 0; i < 1000; i++ {
    results = append(results, i)
}
// · Starts at cap=1000 · every append hits the fast path
// For 1000 elements: 0 growslice calls, 0 dead arrays, 1
allocation total
results := make([]int, 0, 1000)
for i := 0; i < 1000; i++ {
    results = append(results, i)
}
```

When you know the size (or even a rough estimate), `make([]T, 0, n)` eliminates the slow path entirely. Every `append` becomes a ~2ns slot write instead of a potential allocation+copy+GC event.

When you don't know the size, `append` is still safe · the amortized cost is O(1) per element thanks to the exponential growth strategy. But in hot paths processing thousands of requests per second, those growslice allocations add up as GC pressure.

---

5. The Full Slice Expression: `s[low:high:max]`

The three-index slice controls the **capacity** of the resulting slice.

```
s := []int{10, 20, 30, 40, 50}
t := s[1:3:4]    // len = high-low = 2,  cap = max-low = 3

  s:  ...............................
      · 10  · 20  · 30  · 40  · 50  ·
      ...............................
               t.array   len=2, cap=3
```

Without the third index, a sub-slice inherits the full remaining capacity:

```
sub := original[1:3]             // cap=4 · append can overwrite
original[3]!
sub2 := original[1:3:3]          // cap=2 · append triggers growslice
· detach
```

Rule of thumb: Use `s[low:high:high]` to prevent accidental mutation of shared data.

---

6. Shared Backing Array · The Mutation Trap

This is the single most common source of slice bugs in Go. Two slices sharing a backing array can silently corrupt each other.

Step-by-Step Lifecycle

```
a := []int{10, 20, 30, 40, 50}   // Step 1: create
b := a[1:3]                        // Step 2: shared backing array
b[0] = 99                          // Step 3: mutates a[1]!
b = append(b, 77)                  // Step 4: overwrites a[3]
(within cap)
b = append(b, 88)                  // Step 5: overwrites a[4]
(within cap)
b = append(b, 66)                  // Step 6: exceeds cap · b
detaches!

  Steps 1-2: b = a[1:3], b shares a's backing array
  a: ··· ...............................
         · 10  · 20  · 30  · 40  · 50  ·   b.len=2, b.cap=4
         ...............................
                  b
  Step 3: b[0] = 99 · a[1] is now 99!
  Steps 4-5: append within cap · overwrites a[3]=77, a[4]=88
  Step 6: len(b)==cap(b) · growslice · NEW backing array
  a: ··· ...............................
         · 10  · 99  · 30  · 77  · 88  ·  · a keeps old array
         ...............................
  b: ··· ...............................................
         · 99  · 30  · 77  · 88  · 66  ·  0  ·  0  ·  0  ·  · NEW array
         ...............................................
         a and b are now COMPLETELY INDEPENDENT
```

How to Safely Detach

```
b := make([]int, len(a[1:3]))     // Method 1: explicit copy
copy(b, a[1:3])
b := a[1:3:3]                      // Method 2: full slice
expression (detach on first append)
b := append([]int(nil), a[1:3]...) // Method 3: append to nil
```

---

7. Copy Semantics

`copy` creates a **completely independent** copy of elements.

```
src := []int{10, 20, 30, 40, 50}
dst := make([]int, 3)
n := copy(dst, src)   // n = 3 · copies min(len(dst), len(src))
elements
```

Under the Hood: `runtime.memmove`

Source: `runtime/memmove_*.s` (assembly, platform-specific)

`copy(dst, src)` compiles to `runtime.memmove(n × sizeof(T) bytes.)`Uses SIMD instructions (AVX2/SSE) for large copies on amd64, REP MOVSB for medium copies, direct MOV for tiny copies. Handles overlapping regions safely.

Copy Semantics Table

```
.....................................................................
· Expression                  · What Happens                        ·
.....................................................................
· n := copy(dst, src)         · Copies min(len(dst), len(src)) elems ·
· copy(s[2:], s[1:])          · Overlapping copy · safe (memmove)    ·
· copy(dst, "hello")          · String · []byte copy, no alloc       ·
· b := a (assignment)         · NOT data copy! 24B header copy only  ·
.....................................................................
```

---

8. Nil Slice vs Empty Slice

These look the same from the outside but differ at the memory level.

```
  Nil slice (var s []int):        {array: nil,       len: 0, cap:
0} · 24 zero bytes
  Empty slice (s := []int{}):     {array: &zerobase, len: 0, cap:
0} · non-nil pointer
```

`runtime.zerobase` (`runtime/malloc.go`) is a single global variable. ALL zero-length allocations point here. It's never dereferenced · just provides a non-nil address.

Behavioral Comparison

```
.....................................................
· Operation            · nil slice    · empty slice  ·
.....................................................
```

```
· len(s)               · 0            · 0            ·
· cap(s)               · 0            · 0            ·
· s == nil             · true         · false ··      ·
· append(s, 1)         · works ·      · works ·      ·
· for range s {}       · 0 iters ·    · 0 iters ·    ·
· json.Marshal(s)      · "null" ··    · "[]"         ·
· reflect.DeepEqual    · nil · []     · [] · nil     ·
· fmt.Sprintf("%#v",s) · []int(nil)   · []int{}      ·
·····————————————————————————————————————————————————
```

The JSON Trap · Production Impact

```
type Response struct {
    Items []string `json:"items"`
}
r1 := Response{}                 // nil:   {"items":null}  · may
break clients
r2 := Response{Items: []string{}} // empty: {"items":[]}   · safe
```

Rule: For API responses, always initialize slices to empty, never leave them nil.

Best Practice

```
var s []int                      // nil · semantic: "no data"
s := []int{}                     // empty · semantic: "data exists,
it's empty"
var results []int
results = append(results, 1)    // works · append handles nil slices
```

---

9. Memory Leaks via Slices

Slices are the #1 source of subtle memory leaks in Go. The GC cannot collect a backing array if ANY slice header still points into it.

Leak 1: Large Backing Array Retained by Small Slice

```
func processData() []byte {
    data := make([]byte, 1<<20)  // 1 MB
    // ... fill data ...
    return data[:3]               // 3 bytes · but 1MB backing array
stays alive!
}
```

Fix: Copy the needed data to a new, small slice:

```
func processData() []byte {
    data := make([]byte, 1<<20)
    result := make([]byte, 3)
    copy(result, data[:3])   // new 3-byte backing array, 1MB
becomes GC-eligible
    return result
}
```

Leak 2: Slice of Pointers · Deleted Elements Still Referenced

When you shrink a slice of pointers, elements beyond the new length but within capacity still hold references:

```
users := []*User{{"A"}, {"B"}, {"C"}, {"D"}}
users = users[:2]   // backing array still holds pointers to C and
D!

  After users = users[:2]:
  Backing array:
  ........................................
  · *User A · *User B · *User C · *User D ·   · C, D outside len but GC sees
them
  ........................................
  len=2, cap=4              ·         ·
                 GC keeps C and D alive!
```

Fix: Nil out elements before shrinking:

```
for i := 2; i < len(users); i++ {
    users[i] = nil   // break the reference
}
users = users[:2]
```

Leak 3: Substrings Retaining the Parent String

Strings are immutable byte slices (`{Data uintptr, Len int}`). Substrings share the parent's backing bytes:

```
huge := loadHugeString()        // 10 MB string
prefix := huge[:10]              // 10 bytes · but 10 MB stays alive!
// Fix:
prefix := strings.Clone(huge[:10])  // Go 1.20+: allocates new
backing bytes
```

---

10. Slice Tricks · Performance Analysis

All tricks below modify slices in-place using `append`, `copy`, and re-slicing. Understanding their allocation behavior is critical for hot paths.

Delete Element at Index i (Order-Preserving)

```
s = append(s[:i], s[i+1:]...)   // O(n), 0 allocs, modifies
original
```

This one-liner does a lot. Let's break it apart step by step.

What Each Part Means

```
s[:i]       // slice from start up to (not including) index i
s[i+1:]     // slice from index i+1 to end
...         // spread operator · unpacks s[i+1:] into individual
arguments for append
```

```
append(a, b...)  // append all elements of b onto a
```

Step-by-Step Example: Delete Index 2 from `[10, 20, 30, 40, 50]`

```
s := []int{10, 20, 30, 40, 50}   // len=5, cap=5
i := 2                            // delete element 30
s = append(s[:2], s[3:]...)
//         ^^^^   ^^^^^
//       [10,20]  [40,50]
```

Step 1 · `s[:2]` **creates a sub-slice:**

```
s[:2] = [10, 20]    (len=2, cap=5, shares backing array with s)
```

Step 2 · `s[3:]` **creates another sub-slice:**

```
s[3:] = [40, 50]    (len=2, shares backing array with s)
```

Step 3 · `append(s[:2], 40, 50)` **writes into the backing array:**

Since `s[:2]` has `len=2, cap=5`, there's room. `append` writes `40` at index 2 and `50` at index 3 · directly in the **original backing array**:

```
BEFORE:
...............................
· 10  · 20  · 30  · 40  · 50  ·
...............................
  [0]   [1]   [2]   [3]   [4]
AFTER append(s[:2], s[3:]...):
...............................
· 10  · 20  · 40  · 50  · 50  ·
...............................
  [0]   [1]   [2]   [3]   [4]
                            ·
                 s has len=4, this slot is
                 inaccessible but still exists
```

The returned slice has `len=4`: `[10, 20, 40, 50]`. Element `30` is gone. Element `50` is duplicated at index 4 but inaccessible (beyond `len`).

Why It's O(n) and 0 Allocations

- **O(n):** `append` must shift every element after index `i` one position left. Internally this is a `memmove` of `(len - i - 1)` elements.
- **0 allocations:** `s[:i]` has the same backing array with enough capacity, so `append` uses the fast path · `growslice`, no new array.

The Gotcha: Original Slice Is Modified

Because this operates on the **same backing array**, any other slice sharing that backing array sees the mutation:

```
original := []int{10, 20, 30, 40, 50}
alias := original[:]                    // shares backing array
original = append(original[:2], original[3:]...)
// original = [10, 20, 40, 50]
// alias    = [10, 20, 40, 50, 50]  · corrupted! alias still has
len=5
```

If other slices reference the same backing array, **copy first**:

```
s2 := make([]int, len(s))
copy(s2, s)
s2 = append(s2[:i], s2[i+1:]...)  // safe · independent backing array
```

Go 1.21+: `slices.Delete`

```
s = slices.Delete(s, i, i+1)   // same operation, clearer intent
```

Under the hood, `slices.Delete` does the same `append` trick but also **zeroes the vacated slot** at the end to prevent memory leaks when the slice holds pointers or structs with pointer fields.

Delete Element at Index i (Unordered · Fast)

```
s[i] = s[len(s)-1]   // swap with last
s = s[:len(s)-1]      // shrink · O(1), 0 allocs
```

Insert Element at Index i

```
s = append(s, zero)      // grow by one (0-1 allocs)
copy(s[i+1:], s[i:])     // shift right · O(n)
s[i] = value
```

Filter In-Place (Zero Allocation)

```
n := 0
for _, v := range s {
    if keep(v) { s[n] = v; n++ }
}
s = s[:n]   // O(n), 0 allocs
```

Reverse

```
for i, j := 0, len(s)-1; i < j; i, j = i+1, j-1 { s[i], s[j] =
s[j], s[i] }
// Or: slices.Reverse(s) · Go 1.21+
```

Tricks Summary Table

Operation	Time	Allocs	Notes
Delete (ordered)	O(n)	0	Preserves order, in-place
Delete (unordered)	O(1)	0	Changes order, in-place
Insert at index	O(n)	0-1	Preserves order
Filter in-place	O(n)	0	Single pass, in-place
Reverse	O(n)	0	In-place
Pop last	O(1)	0	In-place
Push (append)	O(1)*	0-1	Amortized O(1)

11. Performance Characteristics

Operation Cost Table

```
.....................................................................
· Operation            · Cost         · Why                         ·
.....................................................................
· make([]T, n)         · ~50-200ns    · mallocgc + zeroing memory   ·
· s[i] (index)         · ~1ns         · Bounds check + load (cached)·
· append (no grow)     · ~2-5ns       · Write element + increment len ·
· append (grow)        · ~100-500ns+  · mallocgc + memmove (amort O(1))·
· copy(dst, src)       · ~0.5ns/byte  · memmove (SIMD on amd64)     ·
· range iteration      · ~1ns/elem    · Sequential = cache-friendly ·
· s[low:high] reslice  · ~0.5ns       · Pointer arithmetic, no copy ·
· len(s), cap(s)       · ~0ns         · Inlined: direct field read  ·
.....................................................................
```

Pre-Allocation: The #1 Performance Optimization

```
// BAD · repeated growslice calls
var results []int
for _, v := range input {
    results = append(results, transform(v))
}
// GOOD · single allocation
results := make([]int, 0, len(input))
for _, v := range input {
    results = append(results, transform(v))
}
// 10K elements: BAD = ~14 allocs + ~20K copies. GOOD = 1 alloc + 0
copies.
```

`sync.Pool` for Hot-Path Slice Reuse

In high-throughput code, reuse slices to avoid repeated allocation:

```
var bufPool = sync.Pool{
    New: func() any {
        b := make([]byte, 0, 4096)
        return &b
    },
}
func handleRequest() {
    bp := bufPool.Get().(*[]byte)
    buf := (*bp)[:0]          // reset length to 0, keep capacity
    buf = append(buf, data...)
    *bp = buf                  // put back (may have grown)
    bufPool.Put(bp)
}
```

Warning: `sync.Pool` objects can be GC'd at any time (survive at most two GC cycles). This is NOT a connection

pool · it's a best-effort recycling bin.

Cache Locality: Why Slices Beat Linked Lists

```
Slice: contiguous memory · CPU prefetcher works perfectly
.................................
· 0 · 1 · 2 · 3 · 4 · 5 · 6 · 7 ·  · one cache line (64 bytes)
.................................    ~1ns per element (L1 cache hits)
Linked list: scattered pointers · cache misses everywhere
.......     .......     .......
· 0 ......... 1 ......... 2 ........ ...
.......     .......     .......      ~5-100ns per element
0x1000       0x5000       0x9000
```

Iteration over a 1M-element slice is typically **10-100x faster** than a linked list of the same size, purely due to cache behavior.

Escape Analysis Tips

```
go build -gcflags='-m' ./...       # what escapes to heap
go build -gcflags='-m -m' ./...    # verbose · see WHY something
escapes
```

---

12. Quick Reference Card

```
SLICE HEADER (24 bytes on 64-bit)   Source: runtime/slice.go
.................................
{array unsafe.Pointer, len int, cap int}
  ·· value type containing a pointer · copies share the backing array
MAKE:  make([]T, len, cap) · runtime.makeslice() · mallocgc(cap ×
sizeof(T))
APPEND: s = append(s, ...) · ALWAYS reassign! len<cap · same array;
len==cap · growslice
GROWTH: 2x for cap < 256, then ~1.25x + 192 (Go 1.18+)
FULL SLICE: s[a:b:c] · len=b-a, cap=c-a · use s[a:b:b] to prevent
shared-array mutation
NIL vs EMPTY: nil={nil,0,0} json·"null" | empty={&zerobase,0,0}
json·"[]"
COPY:  n := copy(dst, src) · min(len(dst), len(src)) · fully
independent (memmove)
MEMORY LEAKS
  1. Small reslice of large array · copy to new slice
  2. Slice of pointers after delete · nil out removed elements
  3. Substring of huge string · strings.Clone()
TOOLS
  go build -gcflags='-m'      # escape analysis
  go build -gcflags='-m -m'   # verbose escape analysis
  go build -gcflags='-S'      # assembly output
  go test -bench=. -benchmem  # benchmark + allocations
  go test -race ./...         # race detector
```

One-Line Summary

A slice is a 24-byte value type `{array, len, cap}` · `array` points to the backing data, `append` returns a new header (must reassign), growth allocates a new backing array via `runtime.growslice`, and any sub-slice shares the backing array until capacity is exceeded. Pre-allocate to avoid growslice, nil-out deleted pointer elements to avoid leaks, and use the full slice expression `s[a:b:b]` to prevent accidental mutation of shared data.

Deep Dive: Go Map Internals · hmap, bmap, Growth & the Concurrent Fatal

---

1. The Runtime Struct: `runtime.hmap`

A map variable in Go is a **pointer to an `hmap` struct** · exactly like channels. When you write `m := make(map[string]int)`, `m` is `*hmap`, not `hmap`. This is why passing a map to a function lets the callee modify it · both hold the same pointer.

Source: `runtime/map.go`

```
type hmap struct {
    count     int            // number of live key-value pairs
(len(m) returns this)
    flags     uint8          // iterator/write/grow state flags
    B         uint8          // log· of bucket count (buckets = 2^B)
    noverflow uint16         // approximate count of overflow
buckets
    hash0     uint32         // hash seed · randomized at map
creation
    buckets   unsafe.Pointer // pointer to array of 2^B bmap
```

```
structs
    oldbuckets unsafe.Pointer // non-nil during growth · points to
old bucket array
    nevacuate uintptr        // evacuation progress counter (bucket
index)
    extra     *mapextra      // overflow bucket pre-allocation &
bookkeeping
}
```

Memory Layout

```
  m := make(map[string]int)
  Stack variable 'm':
  ...................
  · *hmap = 0xc00008 ...............................................
  ...................                                               .

.
  Heap: hmap struct

  ..................................................................
  · count      = 0          // no entries yet                      ·
  · flags      = 0x00       // no active iterators, no writes      ·
  · B          = 0          // 2^0 = 1 bucket (minimum)            ·
  · noverflow  = 0          // no overflow buckets                 ·
  · hash0      = 0xa3f7c291 // random seed (unique per map)        ·
  · buckets   ····· [ bmap_0 ]   (array of 2^B = 1 bucket)        ·
  · oldbuckets = nil        // not growing                         ·
  · nevacuate  = 0          // nothing to evacuate                 ·
  · extra      = nil        // no overflow bookkeeping yet         ·
  ..................................................................
```

Key Fields Explained

```
.......................................................................
· Field        · Purpose
  ·
.......................................................................
· count        · Live entries. len(m) reads this directly · O(1)
·
· flags        · Bit flags: hashWriting (0x04), iterator (0x01),
  ·
·              · oldIterator (0x02), sameSizeGrow (0x08)
  ·
· B            · log·(bucket count). B=3 means 8 buckets. B=0 = 1 bucket
·
· noverflow    · Approximate overflow bucket count · triggers same-size
·
·              · grow when too many overflows accumulate
  ·
· hash0        · Random seed generated at make(). Prevents hash
flooding  ·
·              · attacks. Also the reason iteration order is randomized
```

```
  .
· buckets      · Current bucket array · 2^B contiguous bmap structs
·
· oldbuckets   · Previous bucket array during incremental growth
  .
· nevacuate    · Index of next old bucket to evacuate · monotonically
·
·              · increasing until all old buckets are moved
  .
· extra        · mapextra: preallocated overflow buckets, pointers for
GC ·
.......................................................................
```

Why a pointer? If `m` were a value type (like a slice header), passing it to a function would copy the header. Mutations inside the function (inserting keys) would allocate new buckets invisible to the caller. The Go team made maps pointer types so mutation is always shared. This also means the zero value is `nil`, not an empty map · Section 9 covers why that matters.

---

2. Bucket Structure: `runtime.bmap`

Each bucket holds exactly **8 key-value pairs**. This is the constant `bucketCnt = 8` in `runtime/map.go`. The bucket layout is carefully designed for performance.

Source: `runtime/map.go`

```
// Compile-time struct (only the tophash is declared in source):
type bmap struct {
    tophash [bucketCnt]uint8  // top 8 bits of hash for each slot
    // Followed by keys, values, and overflow pointer · laid out by
compiler
}
```

The compiler generates the actual layout. Keys and values are stored in **separate arrays**, not interleaved as `key0, val0, key1, val1, ...`. This avoids padding waste.

Detailed Memory Layout

```
  Single bucket: bmap for map[string]int (key=string=16B,
value=int=8B)
  Offset  Contents
  ......  ..............................................................
  0x00    ...........................................................
          · tophash[0] · tophash[1] · ... · tophash[7]            ·
          ·  (1 byte)  ·  (1 byte)  ·     ·  (1 byte)  = 8 bytes  ·
  0x08    ...........................................................
          · key[0]  (string = 16 bytes: ptr + len)                ·
  0x18    · key[1]  (16 bytes)                                    ·
  0x28    · key[2]  (16 bytes)                                    ·
  ...     · ...                                                   ·
  0x78    · key[7]  (16 bytes)                                    ·
  0x88    ...........................................................
          · val[0]  (int = 8 bytes)                               ·
  0x90    · val[1]  (8 bytes)                                     ·
```

```
...     · ...                                                    ·
0xC0    · val[7]  (8 bytes)                                      ·
0xC8    ··————————————————————————————————————————————————————··
        · overflow *bmap  (8 bytes · pointer to next bucket)     ·
0xD0    ··————————————————————————————————————————————————————··
Total bucket size = 8 + (8×16) + (8×8) + 8 = 208 bytes
```

Why Keys and Values Are Separated

```
INTERLEAVED (how you might expect · Go does NOT do this):
··————————————————————————————————————————————————————————————————————··
· key[0] (string)  · pad (8B)   ·val[0]   · key[1] (string)  · pad (8B)  ·...
· 16 bytes         · WASTED     · 8 bytes · 16 bytes         · WASTED    ·
··————————————————————————————————————————————————————————————————————··
For map[int8]int64: each pair would need 7 bytes of padding
between key and value.
SEPARATED (what Go actually does):
··————————————————————————————————————————————————————————··
· key[0]·key[1]·...·key[7]         · val[0]·val[1]·...·val[7] ·
· all 8 keys packed together       · all 8 values packed      ·
··————————————————————————————————————————————————————————··
No padding waste. map[int8]int64 saves 7 × 8 = 56 bytes per
bucket.
```

Tophash · The Fast-Reject Filter

Each `tophash[i]` stores the **top 8 bits** of the hash for the key in slot `i`. During lookup, the runtime compares `tophash` bytes before doing a full key comparison. Since tophash fits in a single cache line (8 bytes), this rejects 255/256 (~99.6%) of non-matching slots without ever touching the actual keys.

```
Special tophash values (runtime/map.go):
··————————————————————————————————————————————————————————————————··
· Name          · Value  · Meaning
·
··————————————————————————————————————————————————————————————————··
· emptyRest     · 0      · This cell AND all higher indexes are empty
·
· emptyOne      · 1      · This cell is empty (but higher ones may not)
·
· evacuatedX    · 2      · Key was evacuated to first half of new array
·
· evacuatedY    · 3      · Key was evacuated to second half
·
· evacuatedEmpty· 4      · Cell is empty AND bucket has been evacuated
·
· minTopHash    · 5      · Minimum valid tophash value for a real key
·
··————————————————————————————————————————————————————————————————··
If hash top bits compute to 0-4, the runtime adds minTopHash (5)
to
disambiguate from the special sentinel values.
```

---

3. Hash Function

Go uses architecture-specific hash functions for performance. On `amd64` with AES-NI, it uses **AES-based hashing** (`runtime.aeshash`). On other architectures, it falls back to `runtime.memhash` (a variant of wyhash/xxhash-style algorithms).

Source: `runtime/hash64.go`, `runtime/asm_amd64.s`

Hash Seed: `hash0`

Every map instance gets a **unique random seed** (`hash0`) assigned at creation time. This has two consequences:

1. **Security:** prevents hash-flooding DoS attacks. An attacker cannot predict which bucket a key will land in, because the seed is different for every map.
2. **Randomized iteration:** since bucket assignments change with the seed, the physical ordering of keys varies per map instance.

```
// runtime/map.go · simplified from makemap()
func makemap(t *maptype, hint int, h *hmap) *hmap {
    h.hash0 = uint32(rand())  // random seed per map
    // ...
}
```

The Full Lookup Path: From Key to Slot

```
Input: key = "user:42", hash0 = 0xa3f7c291, B = 3 (8 buckets)
Step 1: HASH
...............................................
· hash = aeshash("user:42", hash0)            ·
·      = 0xb7e1_5a3f_928d_4c01   (64-bit hash) ·
...............................................
Step 2: BUCKET INDEX (low B bits)
...............................................
· bucket = hash & (2^B - 1)                   ·
·        = 0x...4c01 & 0x07                   ·
·        = 1  (bucket index)                  ·
...............................................
         Low bits select the bucket ........
Step 3: TOPHASH (top 8 bits of hash)
...............................................
· top = uint8(hash >> (64 - 8))               ·
·     = uint8(0xb7)                           ·
·     = 183                                   ·
...............................................
         Top bits form the fast-compare tag ··
Step 4: SCAN bucket 1's tophash array
.........................................................
· bucket[1].tophash = [0x3a, 0xb7, 0x00, 0x00, ...]      ·
·                           ^^^^                          ·
·                     match at slot 1! · compare full key ·
.........................................................
Step 5: FULL KEY COMPARE
...............................................
· bucket[1].keys[1] == "user:42" ?            ·
```

```
· · YES · return bucket[1].values[1]          ·
.............................................
```

Why low bits for bucket, high bits for tophash? During growth, the bucket count doubles (B increases by 1). The new bit that becomes significant is the next-lowest bit. A key either stays in bucket `i` or moves to bucket `i + 2^(B-1)`. The tophash (high bits) remains valid · no need to recompute it. This is an elegant design enabling incremental evacuation (Section 6).

---

4. Step-by-Step: Map Lookup (`m[key]`)

Source: `runtime/map.go` ·`mapaccess1()` (single return), `mapaccess2()` (comma-ok)

Trace: `v := m["user:42"]`

```
  mapaccess1(t *maptype, h *hmap, key unsafe.Pointer)
unsafe.Pointer
  ................................................................
  · 1. CHECK: is h == nil or h.count == 0?                        ·
  ·    · YES: return pointer to zero value (safe, not a panic)    ·
  ·    · NO: continue                                             ·
  ................................................................
  · 2. CHECK: flags & hashWriting != 0?                           ·
  ·    · YES: fatal("concurrent map read and map write") · CRASH  ·
  ·    · NO: continue                                             ·
  ................................................................
  · 3. HASH: hash = t.hasher(key, uintptr(h.hash0))              ·
  ·    Compute 64-bit hash of "user:42" with this map's seed      ·
  ................................................................
  · 4. BUCKET: m = 1<<h.B - 1  (bucket mask)                     ·
  ·    bucket = hash & m  · index into h.buckets array            ·
  ................................................................
  · 5. GROWING? if h.oldbuckets != nil                            ·
  ·    · old bucket may not be evacuated yet                      ·
  ·    · check if oldbuckets[hash & old_mask] is evacuated        ·
  ·    · if NOT evacuated, search there instead                   ·
  ................................................................
  · 6. TOPHASH: top = tophash(hash)                               ·
  ·    Extract top 8 bits, adjust if < minTopHash (5)             ·
  ................................................................
  · 7. SCAN: for each bucket in overflow chain:                   ·
  ·      for i := 0; i < 8; i++ {                                 ·
  ·        if b.tophash[i] != top {                               ·
  ·          if b.tophash[i] == emptyRest { break }  // done early ·
  ·          continue                                             ·
  ·        }                                                      ·
  ·        k := bucket.key(i)  // pointer arithmetic to key slot  ·
  ·        if t.key.equal(key, k) {                               ·
  ·          return bucket.value(i)  // FOUND · return value ptr  ·
  ·        }                                                      ·
  ·      }                                                        ·
  ·      b = b.overflow  // follow overflow chain                 ·
  ................................................................
```

```
· 8. MISS: return pointer to zero value                          ·
·    (a static zero-sized allocation, safe to read)              ·
.................................................................
```

The Comma-Ok Idiom

```
v, ok := m["user:42"]   // calls mapaccess2() instead of
mapaccess1()
```

`mapaccess2()` is identical to `mapaccess1()` but returns a second `bool`:

```
mapaccess2() returns:
.............................................
· Found · return (pointer to value, true)    ·
· Miss  · return (pointer to zero, false)    ·
.............................................
```

This is how you distinguish "key exists with zero value" from "key does not exist":

```
count, ok := m["page_views"]
// ok == true,  count == 0  · key exists, value is genuinely 0
// ok == false, count == 0  · key does not exist, count is zero value
```

Fast-Path Variants

The runtime also has type-specialized lookup functions to avoid the overhead of generic `mapaccess1()`:

```
  runtime/map_fast32.go  · mapaccess1_fast32()   // 4-byte keys
(int32, uint32)
  runtime/map_fast64.go  · mapaccess1_fast64()   // 8-byte keys
(int64, uint64, pointers)
  runtime/map_faststr.go · mapaccess1_faststr()  // string keys
```

These avoid indirect calls through `t.hasher` and `t.key.equal`, using inline hash computation and comparison. The compiler selects the appropriate variant at build time.

---

5. Step-by-Step: Map Assignment (`m[key] = value`)

Source: `runtime/map.go` ·`mapassign()`

Trace: `m["user:42"] = 100`

```
mapassign(t *maptype, h *hmap, key unsafe.Pointer) unsafe.Pointer
.................................................................
· 1. CHECK: is h == nil?                                         ·
·    · YES: panic("assignment to entry in nil map")              ·
·    · NO: continue                                              ·
.................................................................
· 2. CHECK: flags & hashWriting != 0?                            ·
·    · YES: fatal("concurrent map writes") · HARD CRASH          ·
·    · NO: set flags |= hashWriting (claim write ownership)     ·
.................................................................
· 3. HASH: hash = t.hasher(key, uintptr(h.hash0))               ·
```

```
· 4. BUCKET: bucket = hash & (1<<h.B - 1)
·    Get pointer to target bucket in h.buckets
· 5. GROWING? if h.oldbuckets != nil
·    · evacuate one old bucket (incremental migration)
·    · this is how growth is amortized over inserts/deletes
· 6. SCAN for existing key OR first empty slot:
·
·    var inserti *uint8       // tophash slot for insertion
·    var insertk, insertv    // key/value slot pointers
·
·    for each bucket in overflow chain:
·      for i := 0; i < 8; i++ {
·        if b.tophash[i] != top {
·          if isEmpty(b.tophash[i]) && inserti == nil {
·            inserti = &b.tophash[i]  // remember first empty
·            insertk = b.key(i)
·            insertv = b.value(i)
·          }
·          if b.tophash[i] == emptyRest { break }
·          continue
·        }
·        k := b.key(i)
·        if !t.key.equal(key, k) { continue }
·        // KEY EXISTS · update value in place
·        b.value(i) = value
·        goto done
·      }
·      b = b.overflow
· 7. GROW CHECK: before inserting a new key, check triggers:
·    a) load factor > 6.5  (count / 2^B > 6.5)
·       · double growth: allocate 2^(B+1) buckets
·    b) too many overflow buckets (noverflow >= 2^min(B, 15))
·       · same-size growth: repack to eliminate overflow chains
·    If triggered: call hashGrow(), restart scan in new buckets
· 8. INSERT: if no empty slot found in existing chain
·    · allocate overflow bucket, link to chain
·    · use first slot of new overflow bucket
·
·    Write tophash[inserti] = top
·    Copy key into insertk slot
·    Return insertv pointer (caller writes value through it)
·    h.count++
· 9. DONE: clear flags &^= hashWriting
```

Load Factor: 6.5

The magic number 6.5 means the map targets an average of **6.5 entries per bucket**. Since each bucket holds 8 slots, this means ~81% occupancy before triggering growth. This was chosen empirically by the Go team as the sweet spot between:

```
  Too low (e.g., 4.0):  wastes memory · many empty slots
  Too high (e.g., 7.5): too many overflow chains · lookup becomes
O(n)
  6.5: ~81% full · one overflow chain per ~3 buckets on average
```

Overflow Bucket Chain

```
  When all 8 slots in a bucket are full and a new key hashes to the
same bucket:
  buckets[3]:
  ......................     ......................
  · tophash[0..7]       ·     · tophash[0..7]       ·
  · keys[0..7]          ·     · keys[0..7]          ·  overflow bucket
  · values[0..7]        ·     · values[0..7]        ·
  · overflow ................. overflow ............... nil
  ......................     ......................
  Each overflow bucket is another full bmap with 8 more slots.
  Long chains degrade performance · this triggers same-size growth.
```

---

6. Map Growth · Incremental Evacuation

Source: `runtime/map.go` ·`hashGrow()`, `growWork()`, `evacuate()`

Go maps **never rehash everything at once**. A map with 1 million entries would cause a multi-millisecond pause if rehashing were synchronous. Instead, Go amortizes the cost: each subsequent `mapassign()` or `mapdelete()` evacuates 1-2 old buckets.

Two Types of Growth

```
.........................................................................
· Trigger              · Action
 ·
.........................................................................
· count/2^B > 6.5      · DOUBLE GROWTH: allocate 2^(B+1) new buckets.
·
· (too full)           · B increments by 1. Each old bucket splits into
 ·
·                      · two new buckets (X = same index, Y = index +
·
·                      · 2^oldB). Reduces load factor by half.
 ·
.........................................................................
· noverflow too high   · SAME-SIZE GROWTH: allocate 2^B new buckets
·
· (too many overflow   · (same count). B stays the same. Repacks
entries ·
· chains, sparse data) · to eliminate overflow chains caused by
deletes. ·
```

```
·                       · Compacts the data without increasing capacity.
 ·
.......................................................................
```

The Growth Sequence

```
  hashGrow() · called from mapassign() when trigger conditions are
met
  ..................................................................
  · 1. Allocate new bucket array: makeBucketArray(B+1 or B)        ·
  · 2. h.oldbuckets = h.buckets   // save old array               ·
  · 3. h.buckets = newBuckets     // install new array             ·
  · 4. h.nevacuate = 0            // start evacuating from index 0 ·
  · 5. h.noverflow = 0            // reset overflow counter        ·
  ·                                                                ·
  · NOTE: no entries are moved yet! The old data is still in       ·
  · oldbuckets. Evacuation happens incrementally.                  ·
  ..................................................................
```

Incremental Evacuation: `evacuate()`

On every `mapassign()` or `mapdelete()` call during growth, the runtime calls `growWork()` which evacuates the bucket at index `nevacuate` (and sometimes one more):

```
  evacuate(t *maptype, h *hmap, oldbucket uintptr)
  For DOUBLE growth (B went from 3 to 4):
  Old bucket array (2^3 = 8 buckets)     New bucket array (2^4 = 16
buckets)
  .........                                .........
  · old[0]·· · · ·evacuate· · · · · · ··· new[0]·  X destination
  ·       ·· · · · · · · · · · · · · ··· new[8]·  Y destination
  .........                                .........
  · old[1]·                                · new[1]·
  ·       ·                                · new[9]·
  .........                                .........
  · old[2]·  ··· nevacuate = 2             · new[2]·
  ·       ·      (next to evacuate)        ·new[10]·
  .........                                .........
  ·  ...  ·                                ·  ...  ·
  .........                                .........
  For each key in old[i]:
    new_hash_bit = hash & (1 << oldB)     // the NEW significant
bit
    if new_hash_bit == 0:
      · goes to new[i]           (X: same index)
    else:
      · goes to new[i + 2^oldB]  (Y: index + old bucket count)
```

Dual Lookup During Evacuation

While `oldbuckets != nil`, every lookup must check whether the target bucket has been evacuated yet:

```
  mapaccess during growth:
```

```
.............................................................
· bucket_idx = hash & new_mask                               ·
· old_bucket_idx = hash & old_mask                           ·
·                                                            ·
· if oldbuckets != nil:                                      ·
·   old_b = oldbuckets[old_bucket_idx]                       ·
·   if NOT evacuated(old_b):   // check tophash for markers  ·
·     search in old_b instead  // data hasn't moved yet       ·
·   else:                                                    ·
·     search in buckets[bucket_idx]  // already evacuated     ·
.............................................................
```

Evacuation Progress

```
Timeline of a growth event (B: 2·3, 4 old buckets · 8 new):
Insert #1: evacuate old[0] · new[0] + new[4]    nevacuate = 1
Insert #2: evacuate old[1] · new[1] + new[5]    nevacuate = 2
Insert #3: evacuate old[2] · new[2] + new[6]    nevacuate = 3
Insert #4: evacuate old[3] · new[3] + new[7]    nevacuate = 4
           ·
           ·· nevacuate == 2^oldB · growth complete!
              h.oldbuckets = nil  (old array eligible for GC)
```

Production implication: during growth, there is a ~2x memory spike (both old and new arrays coexist). For maps with millions of entries, this can cause OOM in memory-constrained containers. Pre-allocate with `make(map[K]V, hint)` to avoid unexpected growth.

---

7. Iteration Randomization

Source: `runtime/map.go` ·`mapiterinit()`, `mapiternext()`

Go **deliberately** randomizes map iteration order. This is not an accident or implementation detail · it is a design decision enforced since Go 1.0 to prevent code from depending on insertion order.

How It Works

```go
// runtime/map.go · simplified
func mapiterinit(t *maptype, h *hmap, it *hiter) {
    // Pick a random starting bucket
    r := uintptr(rand())
    it.startBucket = r & bucketMask(h.B)
    // Pick a random starting offset WITHIN that bucket
    it.offset = uint8(r >> h.B & (bucketCnt - 1))
    it.bucket = it.startBucket
    // ...
}
```

The Iterator Struct: `hiter`

```
runtime.hiter
.............................................................
· key         unsafe.Pointer  // current key (for range loop)  ·
```

```
· elem        unsafe.Pointer  // current value                 ·
· t           *maptype        // map type descriptor            ·
· h           *hmap           // the map being iterated         ·
· buckets     unsafe.Pointer  // bucket array at iter start     ·
· bptr        *bmap           // current bucket pointer         ·
· startBucket uintptr         // random starting bucket index   ·
· offset      uint8           // random starting offset (0-7)   ·
· wrapped     bool            // has the iterator wrapped around·
· B           uint8           // B at iteration start           ·
· i           uint8           // current index within bucket    ·
· bucket      uintptr         // current bucket index           ·
· checkBucket uintptr         // for growth-during-iteration    ·
.................................................................
```

Iteration Walk Order

```
B = 2 (4 buckets), random startBucket = 2, random offset = 5
Walk order (bucket:slot):
2:5 · 2:6 · 2:7 · 2:0 · 2:1 · 2:2 · 2:3 · 2:4  (bucket 2, then overflow)
3:5 · 3:6 · 3:7 · 3:0 · 3:1 · 3:2 · 3:3 · 3:4  (bucket 3)
0:5 · 0:6 · 0:7 · 0:0 · 0:1 · 0:2 · 0:3 · 0:4  (bucket 0 · wrapped)
1:5 · 1:6 · 1:7 · 1:0 · 1:1 · 1:2 · 1:3 · 1:4  (bucket 1)
·· starts at offset 5 within each bucket, wraps around to 0-4
Every slot across all buckets (including overflow chains) is
visited exactly once.
```

Iteration During Growth

If the map is growing while being iterated, the iterator must handle the case where some old buckets are evacuated and some are not:

```
Iterator snapshot: B_at_start, buckets_at_start
For each bucket to visit:
  if oldbuckets != nil AND old bucket not evacuated:
    · iterate from old bucket, but SKIP keys that would
      belong to the other half after evacuation
  else:
    · iterate from new bucket normally
```

This guarantees that each key is returned **exactly once**, even during growth.

---

8. Delete Operation

Source: `runtime/map.go` ·`mapdelete()`

Trace: `delete(m, "user:42")`

```
mapdelete(t *maptype, h *hmap, key unsafe.Pointer)
.................................................................
· 1. CHECK: h == nil or h.count == 0 · return (no-op)           ·
· 2. CHECK: flags & hashWriting · fatal("concurrent map writes")·
· 3. Set flags |= hashWriting                                   ·
```

```
· 4. HASH: hash = t.hasher(key, uintptr(h.hash0))              ·
· 5. BUCKET: bucket = hash & (1<<h.B - 1)                      ·
· 6. GROWING? · evacuate one old bucket (incremental)           ·
· 7. SCAN: find key in bucket chain (same as lookup)            ·
·    Found?                                                     ·
·    ·· Clear the key memory (memclr for GC · release references)·
·    ·· Clear the value memory (memclr for GC)                  ·
·    ·· Set tophash[i] = emptyOne                               ·
·    ·· Compact: if tophash[i+1] == emptyRest, upgrade emptyOne  ·
·    ·          entries backward to emptyRest for faster scans  ·
·    ·· h.count--                                               ·
·    ·· Break                                                   ·
·    Not found? · no-op (deleting non-existent key is safe)      ·
· 8. Clear flags &^= hashWriting                                ·
.................................................................
```

Maps Never Shrink

```
.................................................................
· CRITICAL: delete() NEVER deallocates buckets.
·
·
·
· If you insert 1 million keys and then delete 999,999 of them,
·
· the map still holds memory for all the buckets that were
allocated ·
· during growth. The bucket array is NOT resized downward.
·
·
·
· The buckets are only freed when the entire map is garbage
·
· collected (no more references to it).
·
·
·
· Workaround: create a new map and copy surviving keys:
·
·   newMap := make(map[K]V, len(oldMap))
·
·   for k, v := range oldMap { newMap[k] = v }
·
·   oldMap = newMap  // old map becomes eligible for GC
·
.................................................................
```

Why? Shrinking would require evacuation in reverse · moving entries from many buckets into fewer buckets. The Go team decided the complexity and latency risk was not worth it. Most maps in production either grow monotonically or get replaced entirely.

---

9. Nil Map vs Empty Map

```
var m1 map[string]int        // nil map · no hmap allocated
m2 := map[string]int{}       // empty map · hmap exists, count=0
m3 := make(map[string]int)   // empty map · same as m2
```

Behavior Comparison

Operation	nil map	empty map
v := m["key"]	returns zero value (safe, no panic)	returns zero value (safe, no panic)
v, ok := m["key"]	ok = false (safe)	ok = false (safe)
len(m)	0 (safe)	0 (safe)
for k, v := range m	0 iterations (safe)	0 iterations (safe)
delete(m, "key")	no-op (safe)	no-op (safe)
m["key"] = 1	PANIC · "assignment to entry in nil map"	works ·
json.Marshal(m)	"null"	"{}"
m == nil	true	false

Why Write Panics on Nil Map

```
  var m map[string]int   // m is a nil pointer · *hmap == nil
  Stack:
  ...................
  · m = nil          ·   No hmap struct exists on the heap.
  ...................    There is no bucket array to insert into.
  m["key"] = 1
  · runtime calls mapassign(t, h, key)
  · h == nil
  · panic("assignment to entry in nil map")
  Reads are safe because mapaccess1() checks h == nil first and
returns
  a pointer to a static zero value without touching any fields.
```

The JSON Gotcha

```
type Response struct {
    Items map[string]int `json:"items"`
}
r1 := Response{}                          // Items is nil
r2 := Response{Items: map[string]int{}}   // Items is empty
json.Marshal(r1)  // {"items":null}    · APIs often reject null
```

```
json.Marshal(r2)  // {"items":{}}      · clean empty object
```

Production rule: initialize maps in constructors to avoid nil/null serialization issues.

---

10. Concurrent Access · The Fatal Race

Maps are **NOT safe for concurrent use**. The runtime does not use any locking internally. Instead, it detects concurrent access and **kills the process** · not with a panic (which can be recovered), but with `fatal()` which is unrecoverable.

Source: `runtime/map.go` · the `hashWriting` flag

How Detection Works

```
  mapassign():                          mapaccess1() (concurrent):
  ............................          ............................
  · flags |= hashWriting    ·           · if flags & hashWriting  ·
  · ... do the insert ...   ·           ·   · fatal() · CRASH    ·
  · flags &^= hashWriting   ·           ·                         ·
  ............................          ............................
  The runtime sets a flag before writing and checks it during
reads.
  This is NOT a mutex · it's a best-effort detection mechanism.
  It catches most concurrent access but is not guaranteed to catch
all races.
```

The Fatal Message

```
fatal error: concurrent map read and map write
fatal error: concurrent map writes
goroutine 42 [running]:
runtime.throw({0x4a7b20, 0x26})
    runtime/panic.go:1077 +0x48
runtime.mapaccess1_faststr(0xc000080060, {0x4a3e10, 0x5})
    runtime/map_faststr.go:12 +0x1a0
This is NOT a panic · recover() cannot catch it.
The process exits immediately. No cleanup, no deferred functions.
```

Solutions

```
  ......................................................................
  · Pattern              · When to use
 .
  ......................................................................
  · sync.Mutex           · Simple cases. Lock for both read and write.
 .
  ·                      · Best when writes are frequent.
 .
  ·                      ·
 .
  · var mu sync.Mutex    ·   mu.Lock()
 .
```

```
  · m := make(map[K]V)  ·   m[key] = val
.
  ·                     ·   mu.Unlock()
 .
  ......................................................................
  · sync.RWMutex        · Read-heavy workloads. Multiple readers can
 .
  ·                     · proceed concurrently, writers get exclusive
 .
  ·                     · access. Best when reads >> writes.
 .
  ·                     ·
 .
  · var mu sync.RWMutex ·   mu.RLock()    // read path
 .
  · m := make(map[K]V)  ·   v := m[key]
.
  ·                     ·   mu.RUnlock()
 .
  ·                     ·
 .
  ·                     ·   mu.Lock()     // write path
  .
  ·                     ·   m[key] = val
 .
  ·                     ·   mu.Unlock()
 .
  ......................................................................
  · sync.Map            · Two specific patterns:
 .
  ·                     · (1) write-once, read-many (config caches)
 .
  ·                     · (2) disjoint key sets per goroutine
 .
  ·                     · For everything else, map + RWMutex is
faster. ·
  ......................................................................
```

sync.Map Internals

`sync.Map` uses a **two-map architecture** to minimize lock contention for reads:

```
  sync.Map
  ...................................................................
  · read  atomic.Pointer[readOnly]  // lock-free read path
.
  ·   ·· readOnly {                                                 ·
  ·        m     map[any]*entry     // immutable snapshot
.
  ·        amended bool             // true if dirty has new keys
.
  ·      }
.
  ·
```

```
.
  · mu    sync.Mutex                // protects dirty
.
  · dirty map[any]*entry            // mutable map, nil when clean
.
  · misses int                      // read misses since last
promote·
  ....................................................................
  Load("key"):
    1. Try read.m["key"] · atomic load, no lock · FAST PATH
    2. Miss + amended? · mu.Lock(), try dirty["key"], misses++
    3. misses >= len(dirty)? · PROMOTE: read.m = dirty, dirty = nil
       (amortized O(1) · promotion copies the map pointer, not
entries)
  Store("key", val):
    1. If key in read.m · atomic CAS the *entry pointer · no lock!
    2. Else · mu.Lock(), add to dirty (and read if needed)
```

Key insight: `sync.Map` shines when most operations are reads to existing keys. The read path is entirely lock-free (atomic pointer load). But if your workload involves frequent writes to new keys, every Store takes the mutex, and `sync.Map` is slower than a simple `map + sync.RWMutex`.

---

11. Key Type Requirements

Map keys must satisfy the `comparable` constraint · they must support `==` and `!=`.

What Can Be a Key

```
  ....................................................................
  · Type                · Key?   · Notes                            ·
  ....................................................................
  · bool                · ·      ·                                  ·
  · int, uint, float*   · ·      · NaN != NaN · entries with NaN keys ·
  ·                     ·        · are unreachable after insert!      ·
  · complex64/128       · ·      · Same NaN caveat                  ·
  · string              · ·      · Most common key type             ·
  · pointer (*T)        · ·      · Compares ADDRESS, not pointed value ·
  · channel             · ·      · Compares channel identity         ·
  · interface           · ·      · Compares dynamic type + value    ·
  ·                     ·        · Panics at runtime if underlying    ·
  ·                     ·        · type is not comparable             ·
  · array [N]T          · ·      · Element-wise comparison. Fixed size ·
  · struct              · ·*     · Only if ALL fields are comparable ·
  ....................................................................
  · slice []T           · ·      · Not comparable (reference type)  ·
  · map[K]V             · ·      · Not comparable                   ·
  · function            · ·      · Not comparable                   ·
  · struct with slice/  · ·      · Struct is non-comparable if any  ·
  · map/func field      ·        · field is non-comparable            ·
  ....................................................................
```

The NaN Trap

```
m := map[float64]string{}
m[math.NaN()] = "hello"
m[math.NaN()] = "world"
len(m)              // 2 · two separate entries!
v := m[math.NaN()]  // "" · cannot retrieve either one!
// NaN != NaN by IEEE 754. The key can never match on lookup.
// These entries are "zombie" · unreachable but counted.
// They'll only be freed when the map is GC'd.
```

Pointer Keys vs Value Keys

```
type Point struct{ X, Y int }
// POINTER keys: compare memory addresses
m1 := map[*Point]string{}
p := &Point{1, 2}
m1[p] = "A"
m1[&Point{1, 2}] = "B"   // different pointer! Two entries.
len(m1) // 2
// STRUCT keys: compare field values
m2 := map[Point]string{}
m2[Point{1, 2}] = "A"
m2[Point{1, 2}] = "B"    // same value! Overwrites.
len(m2) // 1
```

Array Keys (underused pattern)

```
// Arrays are comparable · great for composite keys
type CacheKey = [3]string  // [method, path, version]
cache := map[CacheKey]Response{}
cache[CacheKey{"GET", "/api/users", "v2"}] = resp
// Avoids string concatenation for composite keys.
// Fixed size is checked at compile time.
```

---

12. Performance Characteristics

Cost Table

```
.............................................................................
· Operation            · Time          · Details
    ·
.............................................................................
· Lookup (hit)         · O(1) avg      · Hash + tophash scan (8 compares)
+   ·
· m[key]               · ~50-150ns     · 1 full key compare. Overflow
chains  ·
·                      ·               · add ~50ns per extra bucket
scanned.  ·
.............................................................................
· Lookup (miss)        · O(1) avg      · Same path, but must scan all 8
   ·
```

```
·                       · ~50-120ns     · tophash entries + overflow chain
    ·
·                       ·               · before confirming miss.
    ·
.............................................................................
· Insert (no growth)    · O(1) avg      · Hash + scan + write key/value.
    ·
· m[key] = val          · ~100-250ns    · Includes tophash update.
    ·
.............................................................................
· Insert (triggers      · O(1) amort.   · hashGrow() allocates new array +
    ·
· growth)               · ~500ns-5·s    · evacuates 1-2 old buckets per
call.  ·
·                       ·               · One-time allocation spike.
    ·
.............................................................................
· Delete                · O(1) avg      · Same as lookup + memclr
key/value.   ·
· delete(m, key)        · ~100-200ns    · No memory is freed.
    ·
.............................................................................
· Iteration             · O(n)          · Visits every bucket + overflow.
    ·
· for k, v := range m   ·               · Cache-unfriendly for sparse
maps.    ·
.............................................................................
· len(m)                · O(1)          · Reads h.count directly.
    ·
.............................................................................
· make(map, hint)       · O(hint)       · Allocates ·hint/6.5· buckets
·
·                       ·               · rounded up to next power of 2.
    ·
.............................................................................
```

Memory Overhead Per Entry

```
  Bucket overhead (per 8 entries):
    8 bytes tophash + 8 byte overflow pointer = 16 bytes overhead
    Per entry: 16/8 = 2 bytes of overhead + key size + value size
  For map[string]int (key=16B, value=8B):
    Per entry: 16 + 8 + 2 = ~26 bytes (vs 24 bytes for the raw
data)
    Overhead: ~8%
  For map[int64]bool (key=8B, value=1B):
    Per entry: 8 + 1 + 2 = ~11 bytes (vs 9 bytes raw)
    But bucket alignment pads values: 8 × 1 byte values · 8 bytes
    Actual per entry: 8 + 1 + 2 = ~11 bytes
    Overhead: ~22%
  Plus: hmap struct (48 bytes) + bucket array pointer alignment
  Plus: ~19% empty slots (load factor 6.5/8 = 81% full)
```

Map vs Slice for Small Collections

```
.................................................................
· Collection Size     · map[K]V             · []struct{K,V}       ·
.................................................................
· < 8 entries         · Overkill. hmap +    · Linear scan is fast. ·
·                     · bucket overhead.    · Cache-friendly. Less ·
·                     · Hash computation    · memory. No hashing.  ·
·                     · cost dominates.     · PREFER THIS.         ·
.................................................................
· 8-50 entries        · About equal.        · Still competitive    ·
·                     · Hash is amortized.  · with sorted + binary ·
·                     ·                     · search.              ·
.................................................................
· > 50 entries        · Clear winner.       · Linear scan is O(n). ·
·                     · O(1) lookup.        · Too slow.            ·
.................................................................
```

Pre-Allocation: `make(map[K]V, hint)`

```
// WITHOUT hint · 7+ growth events for 10,000 entries:
m := map[string]int{}
for i := 0; i < 10000; i++ {
    m[fmt.Sprint(i)] = i  // triggers growth at ~8, ~52, ~416,
~3328, ...
}
// WITH hint · zero growth events:
m := make(map[string]int, 10000)
for i := 0; i < 10000; i++ {
    m[fmt.Sprint(i)] = i  // all buckets pre-allocated
}
```

The hint is rounded up: `make(map[K]V, 10000)` allocates `·10000/6.5· = 1539` buckets, rounded to next power of 2 = 2048 buckets (B=11). This is a **hint**, not a hard cap · the map will still grow if you exceed it. But avoiding growth eliminates the 2x memory spike and reduces GC pressure from abandoned old bucket arrays.

Verify with benchmarks:

```
go test -bench=BenchmarkMapInsert -benchmem ./...
# Without hint: ~15 allocs/op (growth events)
# With hint:    ~1 allocs/op  (initial allocation only)
```

---

13. Quick Reference Card

```
MAP VARIABLE
............
m is *hmap (pointer to runtime.hmap struct on the heap)
Like channels: passed by pointer, zero value is nil.
BUCKET STRUCTURE
................
bmap = [8]tophash + [8]keys + [8]values + *overflow
Keys and values stored separately to minimize padding.
Tophash: top 8 bits of hash · 99.6% fast rejection.
```

```
HASH & LOOKUP
.............
hash(key, hash0) · low B bits = bucket index, top 8 bits = tophash
Scan 8 tophash bytes · match · full key compare · return value
Type-specialized: map_fast32, map_fast64, map_faststr
GROWTH
......
Trigger: load factor > 6.5 OR too many overflow buckets.
Double growth: 2^B · 2^(B+1), keys split by new hash bit.
Same-size growth: repack to eliminate overflow chains.
Incremental: 1-2 old buckets evacuated per insert/delete.
During growth: dual lookup (check old if not yet evacuated).
NEVER SHRINKS
.............
delete() clears tophash + key + value. Buckets stay allocated.
Workaround: create new map, copy survivors, drop old map.
NIL vs EMPTY
............
nil map:   read safe, write panics, json · "null"
empty map: read safe, write safe,  json · "{}"
Always initialize maps before writing.
CONCURRENCY
...........
No built-in safety. Concurrent read+write · fatal (unrecoverable).
sync.Mutex: simple, works for all patterns.
sync.RWMutex: read-heavy workloads, multiple concurrent readers.
sync.Map: write-once-read-many or disjoint goroutine key sets.
KEY TYPES
.........
Must be comparable (==). No slices, maps, or functions.
Pointers: compare address. Structs: compare all fields.
NaN float keys: unreachable after insert (NaN != NaN).
PERFORMANCE
...........
Lookup/Delete: O(1) avg, ~50-200ns.
Insert: O(1) amortized, ~100-250ns (no growth).
Pre-allocate: make(map[K]V, hint) avoids growth events.
For < 8 entries: prefer sorted slice + linear scan.
TOOLS
.....
go test -race ./...            # detect concurrent map access
go test -bench=. -benchmem     # measure map allocation cost
go build -gcflags='-m'         # escape analysis for map values
```

One-Line Summary

A map is a `*hmap` pointer to a hash table of 8-slot buckets, using tophash bytes for fast rejection and incremental evacuation for growth · it never shrinks, randomizes iteration by design, and kills your process on concurrent read/write.

---

13 · String Internals Deep Dive

How Go represents, stores, and manipulates strings under the hood · and why strings are "read-only slices of bytes."

---

1. The String Header · A 2-Word Struct

A string in Go is not an object, not a class · it's a **2-word struct**:

```
// Source: runtime/string.go
type stringStruct struct {
    str unsafe.Pointer  // pointer to backing byte array
(read-only)
    len int             // number of bytes (NOT characters)
}

string header (16 bytes on 64-bit):
...............................................
·  str unsafe.Pointer  ·  len int             ·
·  (points to bytes)   ·  (byte count)        ·
...............................................
```

Compare with a slice header (24 bytes):

```
slice header:   { ptr, len, cap }   · 3 words (24 bytes)
string header:  { ptr, len }        · 2 words (16 bytes) · no cap,
because immutable
```

There's no `cap` field because strings can't grow · they're immutable. There's nothing to "grow into," so capacity is meaningless.

What `len()` Returns

```
s := "Hello"
len(s)  // 5 · five BYTES, not five characters
s = "中"
len(s)  // 6 · two characters, but 6 BYTES (3 bytes per Chinese
```

```
character in UTF-8)
```

`len()` reads the `len` field of the string header directly · it's an **O(1)** operation, inlined by the compiler. It does not count characters.

---

2. Strings Are Immutable · Why and How

Once created, a string's backing bytes **cannot be modified**. There is no `s[0] = 'X'`.

```
s := "hello"
s[0] = 'H'    // · compile error: cannot assign to s[0] (value of
type byte)
```

Why Immutability?

1. Safe concurrent access. Multiple goroutines can read the same string without locks. No data race is possible because nobody can write.

2. Safe to share backing data. Substrings and string copies can point to the same bytes without risk of mutation:

```
s := "hello world"
sub := s[0:5]     // "hello" · shares the same backing bytes as s
// If strings were mutable, modifying s would corrupt sub
```

3. Strings can be map keys. Map keys must be comparable and stable. If a string could be modified after insertion, the hash would be wrong and lookup would break.

4. The compiler can optimize. String literals are stored in the read-only data segment of the binary. The OS can memory-map them and share across processes.

How Immutability Is Enforced

The compiler simply **refuses to compile** assignments to string indices. At the runtime level, the backing bytes for string literals live in the `.rodata` (read-only data) section of the binary. Attempting to write there via `unsafe` would cause a **segfault** from the OS memory protection.

The Cost of Immutability

Every "modification" creates a **new string** with a **new backing array**:

```
s := "hello"
s = s + " world"   // allocates new 11-byte array, copies "hello" +
" world"
                    // old "hello" backing bytes become GC-eligible
```

This is why string concatenation in loops is expensive · each `+=` allocates.

---

3. Bytes vs Runes vs Characters

This is the most important mental model for strings in Go. There are **three levels**:

```
"Hello, ··"
BYTES (what the computer sees):
.................................................................
```

```
· 48 · 65 · 6C · 6C · 6F · 2C · 20 · E4 · B8 · 96 · E7 · 95 · 8C ·
.................................................................
  H    e    l    l    o    ,  (sp)  ··· · ···  ··· · ···
                                    3 bytes     3 bytes
len("Hello, ··") = 13 bytes
RUNES (Unicode code points · what Go uses):
.........................................................
· 'H' · 'e' · 'l' · 'l' · 'o' · ',' · ' ' ·  '·'  ·  '·'  ·
.........................................................
len([]rune("Hello, ··")) = 9 runes
CHARACTERS (what humans see):
H  e  l  l  o  ,     ·  ·     = 9 visible characters (in this case =
runes)
```

What Is a Rune?

```
type rune = int32  // alias for int32 · holds any Unicode code point
```

A rune is a **Unicode code point** · a number that identifies a character in the Unicode standard. `'·'` is rune `U+4E16` = `19990` in decimal.

UTF-8 Encoding · Variable Width

Go strings are **UTF-8 encoded**. Each rune takes 1-4 bytes:

```
.......................................................
· Character Range      · Bytes · Examples              ·
.......................................................
· U+0000 - U+007F     · 1     · ASCII: A, z, 9, @     ·
· U+0080 - U+07FF     · 2     · é, ñ, ·, ×            ·
· U+0800 - U+FFFF     · 3     · ·, ·, ·, ·           ·
· U+10000 - U+10FFFF  · 4     · ·, ·, ·              ·
.......................................................
```

The Implication

Indexing by byte is NOT indexing by character:

```
s := "café"
s[3]           // 0xC3 · first byte of 'é', NOT the letter 'é'
len(s)         // 5 bytes (c=1, a=1, f=1, é=2)
len([]rune(s)) // 4 runes (c, a, f, é)
```

This is why you can't do `s[i]` and expect a character · you get a **byte**.

When Characters · Runes

Some visible characters are made of **multiple runes** (combining characters):

```
s := "é"        // could be 1 rune (U+00E9) or 2 runes (e + U+0301
combining accent)
s = "·····"  // 5 runes: · + ZWJ + · + ZWJ + · · but 1 visible "character"
```

For most server-side Go code, **rune = character** is close enough. If you need true grapheme cluster counting (emoji,

combining marks), use `golang.org/x/text/unicode/norm` or third-party libraries.

---

4. String Iteration · Two Different Loops

`for i` · Iterates Over Bytes

```
s := "Go··"
for i := 0; i < len(s); i++ {
    fmt.Printf("byte[%d] = %x\n", i, s[i])
}
// byte[0] = 47  (G)
// byte[1] = 6f  (o)
// byte[2] = e4  ·
// byte[3] = b8  ··· · (3 bytes)
// byte[4] = 96  ·
// byte[5] = e7  ·
// byte[6] = 95  ··· · (3 bytes)
// byte[7] = 8c  ·
```

`for range` · Iterates Over Runes (UTF-8 decoded)

```
s := "Go··"
for i, r := range s {
    fmt.Printf("rune at byte %d = %c (U+%04X)\n", i, r, r)
}
// rune at byte 0 = G (U+0047)
// rune at byte 1 = o (U+006F)
// rune at byte 2 = · (U+4E16)   · jumped from byte 2 to byte 5
// rune at byte 5 = · (U+754C)
```

Key difference: `for range` on a string automatically **decodes UTF-8**. The index `i` is the **byte position**, and `r` is the **decoded rune**. Notice the index jumps from 2 to 5 · it skipped the 3 bytes that encode .

What Happens with Invalid UTF-8?

```
s := "ab\xff\xfec"  // invalid UTF-8 bytes
for _, r := range s {
    fmt.Printf("%c ", r)
}
// a b · · c
// Invalid bytes produce U+FFFD (replacement character)
```

`for range` is safe · it never panics on invalid UTF-8. It substitutes `U+FFFD`.

---

5. String · Byte Slice Conversions · The Hidden Cost

`[]byte(s)` · String to Byte Slice

```
s := "hello"
b := []byte(s)   // allocates new 5-byte array, copies "hello" into
```

```
it
```

This allocates and copies. The runtime must copy because:

- Strings are immutable · the backing bytes must not be modified
- Byte slices are mutable · the caller expects to modify `b`
- Sharing the same backing would violate string immutability

`string(b)` · Byte Slice to String

```
b := []byte{72, 101, 108, 108, 111}
s := string(b)   // allocates new backing array, copies bytes
```

Also allocates and copies. The runtime must copy because:

- If it shared the backing array, modifying `b[0]` later would change `s`
- That would violate string immutability

The Cost

```
// In a hot loop processing 50k requests/sec:
func handle(s string) {
    b := []byte(s)     // allocation + copy · 50k allocations/sec
    process(b)
    result := string(b) // another allocation + copy · 50k more
    return result
}
```

Each conversion is `O(n)` in the length of the string. In hot paths, this creates significant GC pressure.

Compiler Optimizations · When It Doesn't Copy

The compiler is smart enough to skip the copy in certain patterns:

```
// 1. Map lookup with []byte key · no allocation
m := map[string]int{"hello": 1}
b := []byte("hello")
_ = m[string(b)]          // compiler optimizes: no copy, temporary
string header
// 2. String comparison · no allocation
if string(b) == "hello" { ... }  // compiler: compare bytes
directly, no alloc
// 3. Range over []byte as string · no allocation
for _, r := range string(b) { ... }  // compiler: decode UTF-8
in-place
```

Zero-Copy Conversion (Go 1.20+ · `unsafe`)

When you're **sure** the byte slice won't be modified:

```
import "unsafe"
b := []byte("hello")
s := unsafe.String(&b[0], len(b))  // zero-copy: s points to b's
backing array
```

```
// ·· DANGER: modifying b now corrupts s · violates string immutability
```

Use only in performance-critical code where you control the byte slice lifecycle.

---

6. Substrings Share Backing Data · Memory Leak Trap

Substrings do **not** copy data. They create a new string header pointing into the **same backing bytes**:

```
huge := loadHugeString()   // 10 MB string
prefix := huge[:10]         // new header: {ptr: same as huge, len:
10}

huge header:    { ptr ··********** [10 MB of bytes...............] }
                                   ·
prefix header:  { ptr ··************, len: 10 }
```

The prefix is only 10 bytes, but the **entire 10 MB backing array** stays alive because `prefix` holds a pointer into it. GC cannot collect the 10 MB until both `huge` and `prefix` are dead.

The Fix

```
// Go 1.20+
prefix := strings.Clone(huge[:10])  // allocates new 10-byte
backing array
// Before Go 1.20
prefix := string([]byte(huge[:10])) // string · []byte (copies 10) ·
string (copies 10)
```

`strings.Clone` explicitly allocates a new backing array, breaking the reference to the original 10 MB.

When This Matters

- Parsing large HTTP response bodies and keeping small substrings
- Extracting fields from large log lines
- Any pattern where a small substring outlives a large parent string

---

7. String Concatenation · Performance Analysis

+ Operator · Simple But Costly

```
s := "hello"
s = s + " " + "world"  // allocates new 11-byte array, copies
everything
```

Each + allocates a new backing array. In a loop, this is **O(n^2)**

```
// · O(n²) · each iteration allocates and copies everything so far
var s string
for i := 0; i < 1000; i++ {
    s += "x"  // iteration 1: copy 1 byte, iteration 2: copy 2, ...
iteration 1000: copy 1000
```

```
}
// Total bytes copied: 1 + 2 + 3 + ... + 1000 = 500,500 copies +
1000 allocations
```

`strings.Builder` · The Right Way

```
// · O(n) · amortized, like slice append
var b strings.Builder
b.Grow(1000)  // optional: pre-allocate if you know the size
for i := 0; i < 1000; i++ {
    b.WriteString("x")
}
s := b.String()
// Total: ~1-3 allocations (grows like a slice), 1000 bytes copied
once each
```

`strings.Builder` internally uses a `[]byte` and calls `append`. It grows with the same strategy as slices (2x, then ~1.25x). The final `String()` call uses `unsafe.String` to convert the `[]byte` to a `string` **without copying** · this isafe because Builder ensures the bytes won't be modified after `String()` is called.

`fmt.Sprintf` · Convenient But Slow

```
s := fmt.Sprintf("%s %s %d", first, last, age)
// Uses reflection internally to inspect types, allocates multiple
intermediate values
```

`fmt.Sprintf` uses `reflect` under the hood to determine types. In hot paths, prefer `strings.Builder` or `strconv` for simple conversions.

`strings.Join` · Best for Known Slices

```
parts := []string{"hello", "world", "go"}
s := strings.Join(parts, ", ")  // "hello, world, go"
// Pre-calculates total length · single allocation · copies each part
once
```

Concatenation Cost Summary

```
.......................................................................
· Method                · Allocations  · When to Use
·
.......................................................................
· s1 + s2               · 1 per +      · 2-3 strings, one-time
·
· s += x (in loop)      · N (O(n²))    · Never in loops                 ·
· strings.Builder       · ~1-3 (amort) · Building strings incrementally
·
· strings.Join          · 1            · Joining a known []string
·
· fmt.Sprintf           · Multiple     · Formatted output, not hot paths
·
· strconv.Itoa/AppendX  · 0-1          · Number · string in hot paths    ·
.......................................................................
```

8. String Comparison and Interning

Comparison with ==

String comparison in Go is **value-based** · it compares the actual bytes, not pointers:

```
a := "hello"
b := string([]byte{'h', 'e', 'l', 'l', 'o'})
a == b   // true · same bytes, even though different backing arrays
```

Under the hood: The runtime first compares `len`. If lengths differ, returns `false` immediately (O(1)). If lengths match, compares bytes via `memequal` (O(n)).

String Interning

String literals in the same binary **may** share backing data. The compiler and linker can deduplicate identical string constants:

```
a := "hello"   // points to .rodata section
b := "hello"   // may point to SAME bytes in .rodata (compiler
decides)
```

But this is a **compiler optimization**, not a language guarantee. Don't rely on pointer equality for strings · always use ==.

Case-Insensitive Comparison

```
// · Correct for ASCII and Unicode
strings.EqualFold("Hello", "hello")   // true
strings.EqualFold("·", "·")          // true (Greek omega)
// · Wrong · only works for ASCII
strings.ToLower(a) == strings.ToLower(b)  // allocates two new
strings just to compare
```

`EqualFold` compares without allocating · it decodes runes and folds case on the fly.

---

9. Strings and the Compiler · Escape Analysis

String Literals Don't Allocate

```
func greet() string {
    return "hello"   // no allocation · points directly to .rodata in
the binary
}
```

String literals live in the binary's read-only data section. Returning a string literal just copies the 16-byte header (pointer + length). The pointer points into the binary itself · no heap allocation, no GC involvement.

Conversions and Concatenation Force Allocation

```
func process(b []byte) string {
    return string(b)        // allocates: must copy bytes to create
immutable backing
}
func combine(a, b string) string {
    return a + b            // allocates: new backing array for
concatenated result
}
```

Passing Strings to `interface{}`

```
func log(msg string) {
    fmt.Println(msg)        // msg escapes to heap · Println takes
any (interface)
}
```

Same principle as slices · boxing into an `eface` requires a heap pointer. For hot-path logging, structured loggers like `slog` avoid this by using typed methods.

---

10. Production Patterns and Best Practices

Pattern 1: Use `[]byte` Internally, `string` at API Boundaries

```
// Internal processing: work with []byte to avoid conversion costs
func processRequest(body []byte) []byte {
    // parse, transform, build response · all as []byte
    return result
}
// API boundary: accept and return string
func HandleRequest(input string) string {
    b := []byte(input)          // one conversion in
    result := processRequest(b)
    return string(result)        // one conversion out
}
```

Pattern 2: Pre-Size `strings.Builder`

```
func buildResponse(items []Item) string {
    // Estimate: ~50 bytes per item
    var b strings.Builder
    b.Grow(len(items) * 50)    // single allocation
    for _, item := range items {
        b.WriteString(item.Name)
        b.WriteByte(',')
    }
    return b.String()
}
```

Pattern 3: Avoid `fmt.Sprintf` in Hot Paths

```
// · Uses reflection, multiple allocations
key := fmt.Sprintf("user:%d:session:%s", userID, sessionID)
// · Zero-reflection, minimal allocations
var b strings.Builder
b.WriteString("user:")
b.WriteString(strconv.Itoa(userID))
b.WriteString(":session:")
b.WriteString(sessionID)
key := b.String()
```

Pattern 4: `strings.Clone` for Long-Lived Substrings

```
func extractToken(header string) string {
    // header is "Bearer eyJhbGci..." (could be large)
    token := header[7:]
    return strings.Clone(token)  // detach from header's backing
bytes
}
```

Pattern 5: Use `strconv.`AppendX for Zero-Alloc Number Formatting

```
// Append directly to an existing []byte · no intermediate string
buf := make([]byte, 0, 64)
buf = strconv.AppendInt(buf, 42, 10)        // "42"
buf = strconv.AppendFloat(buf, 3.14, 'f', 2, 64)  // "3.14"
```

---

11. Quick Reference Card

```
STRING HEADER (16 bytes on 64-bit)        Source: runtime/string.go
.................................
  str unsafe.Pointer  ·  backing byte array (immutable)
  len int             ·  byte count (NOT character count)
KEY RULES
.........
  len(s)              ·  byte count, O(1)
  len([]rune(s))      ·  character count, O(n) · allocates rune slice
  utf8.RuneCountInString(s)  ·  character count, O(n) · no allocation
  s[i]                ·  byte at index i (NOT character)
  for i, r := range s ·  iterate runes (UTF-8 decoded)
  for i := 0; i < len(s) ·  iterate bytes (raw)
IMMUTABILITY
............
  s[0] = 'X'          ·  compile error
  s + " world"        ·  new string, new backing array
  s[:5]               ·  new header, SHARED backing bytes
CONVERSIONS (both allocate + copy unless compiler optimizes)
............
  []byte(s)           ·  mutable copy of string bytes
  string(b)           ·  immutable string from byte slice
  []rune(s)           ·  slice of Unicode code points
  string(r)           ·  string from single rune
```

```
PERFORMANCE
...........
  s += x (in loop)    ·  O(n²) · never do this
  strings.Builder     ·  O(n) amortized · use for building strings
  strings.Join        ·  single allocation · use for joining slices
  strings.Clone       ·  detach substring from parent (Go 1.20+)
  strconv.Itoa        ·  int to string (no reflection)
  strconv.AppendInt   ·  append int to []byte (zero alloc)
TOOLS
.....
  go build -gcflags='-m' ./...   ·  see string escape analysis
  go test -bench=. -benchmem     ·  measure allocations per operation
```

One-Line Summary

A string is a 16-byte immutable `{pointer, len}` header · essentially a read-only slice without capacity. Every "modification" creates a new backing array. `len()` counts bytes not characters. Use `strings.Builder` for concatenation, `[]rune` for character access, and `strings.Clone` to detach substrings from large parents.

---

14 · Variable Declaration: `var` vs `:=` vs Explicit Type

When to use which form, what the compiler does, and the idiomatic conventions.

The Three Forms

```
var x int = 5     // Form 1: var + explicit type + value
var x = 5         // Form 2: var + inferred type
x := 5            // Form 3: short declaration + inferred type
```

All three compile to identical machine code. The difference is purely about readability, context, and what the compiler infers.

Form-by-Form Breakdown

Form 1: `var x Type = value` · Explicit Type

```
var count int = 0
var name string = "Go"
var r io.Reader = &MyStruct{}
```

When to use:

- When the **inferred type is not what you want**:

```
var r io.Reader = &MyStruct{}   // you want io.Reader, not
*MyStruct
```

```
var n int64 = 42                // you want int64, not int
var f float64 = 1               // you want float64, not int
```

- When making the type explicit **improves readability** in complex code

Under the hood: The compiler skips inference · it uses the type you declared and checks that the value is assignable to it.

Form 2: `var x = value` · Inferred Type

```
var maxRetries = 3
var appName = "myservice"
var timeout = 30 * time.Second
```

When to use:

- **Package-level variables** (`:=` is not allowed at package level):

```
package main
var Version = "1.0.0"   // · package level
Version := "1.0.0"      // · compile error: non-declaration statement
outside function body
```

- When you want inference but `:=` isn't available

Under the hood: The compiler infers the type from the right-hand side, same as `:=`.

Form 3: `x := value` · Short Declaration

```
count := 0
name := "Go"
result := computeSomething()
```

When to use:

- **Inside functions · this is the default Go style**
- Most variable declarations in Go code use this form
- It's concise and the type is obvious from the value

Under the hood: Syntactic sugar for `var x = value`. Identical compiled output.

The Zero Value Form: `var x Type` (No Assignment)

```
var count int        // 0
var name string      // ""
var ok bool          // false
var s []int          // nil
var m map[string]int // nil
var err error        // nil
```

This is the ONLY form where `var` has no `:=` equivalent. You cannot write:

```
count :=       // · what value? Compile error.
```

When to use:

- When you want the **zero value** and assigning later
- Common pattern: declare before `if/switch`, assign inside, use after:

```
var result int
if condition {
    result = computeA()
} else {
    result = computeB()
}
// use result here
```

Where Each Form Is Allowed

```
.............................................................
· Form                · Inside Function · Package Level    ·
.............................................................
· var x Type = value  · ·              · ·                ·
· var x = value       · ·              · ·                ·
· x := value          · ·              · · not allowed    ·
· var x Type          · ·              · ·                ·
.............................................................
```

Key rule: `:=` only works inside function bodies. At package level, you must use `var`.

Type Inference: What the Compiler Decides

When you omit the type, the compiler infers from the value:

```
x := 42              // int (not int32, not int64 ·
platform-dependent int)
x := 42.0            // float64 (not float32)
x := "hello"         // string
x := true            // bool
x := 'A'             // rune (which is int32)
x := 3 + 4i          // complex128
x := []int{1, 2, 3}  // []int
x := map[string]int{} // map[string]int
x := &User{}          // *User
```

Gotcha · numeric defaults:

```
x := 42       // int · NOT int64
y := 42.0     // float64 · NOT float32
// If you need a specific numeric type, use explicit form:
var x int64 = 42
var y float32 = 42.0
```

The `:=` Redeclaration Rule

`:=` can **redeclare** a variable if at least one variable on the left is new:

```
x := 5
x := 10           // · compile error: no new variables on left side
x, y := 5, "hi"
x, z := 10, true  // · z is new, so x is reassigned (not redeclared)
```

This is commonly seen with `err`:

```
result, err := doFirst()     // err declared
output, err := doSecond()    // err reassigned (output is new)
```

Gotcha · shadowing in inner scopes:

```
x := 5
if true {
    x := 10    // · this is a NEW x, shadows the outer x
    fmt.Println(x)  // 10
}
fmt.Println(x)      // 5 · outer x unchanged!
// Fix: use = (assignment) instead of := (declaration)
if true {
    x = 10     // · assigns to the outer x
}
```

Grouped `var` Declarations

At package level, group related variables:

```
var (
    MaxRetries = 3
    Timeout    = 30 * time.Second
    AppName    = "myservice"
)
```

This is also used for compile-time interface checks:

```
var _ io.Reader = (*MyStruct)(nil)  // compile error if MyStruct
doesn't implement io.Reader
```

The Idiomatic Rules

```
.......................................................................
·  1. Inside functions · use :=  (default, most common)             ·
·  2. Zero values · use var x Type  (no := equivalent)              ·
·  3. Package level · use var  (:= not allowed)                     ·
·  4. Explicit interface type · use var r InterfaceType = value      ·
·  5. Explicit numeric type · use var n int64 = 42                  ·
·  6. Group related package vars · use var ( ... ) block            ·
.......................................................................
```

Quick Reference

```
DECLARATION FORMS
.................
  var x int = 5        explicit type, explicit value
  var x = 5            inferred type, explicit value
  x := 5               inferred type, explicit value (function
only)
  var x int            explicit type, zero value
COMPILER BEHAVIOR
.................
  All forms with same type+value · identical compiled output
  := is syntactic sugar for var x = value
  Type inference: int, float64, string, bool, rune for literals
SCOPE RULES
...........
  := creates a NEW variable in current scope (can shadow outer)
  = assigns to EXISTING variable (no shadowing)
  := with multiple returns: redeclares if at least one var is new
```

One-Line Summary

`var` and `:=` produce identical compiled code · the choice is about **context** (package vs function level), **readability** (explicit vs inferred type), and **zero values** (only `var x Type` can declare without assigning).

Go's Automatic Pointer Magic: Auto-Address & Auto-Dereference

Go's compiler does **two silent tricks** to make your code less verbose. Understanding exactly when and why they happen is the key.

The Two Tricks

Name	What Go does silently	Example
Auto-address	`c.Method()` · `(&c).Method()`	When method needs `*T` but you have `T`
Auto-deref	`p.Field` · `(*p).Field`	When accessing fields on a `*T`

Trick 1: Auto-Dereference (field & method access on pointers)

Rule: When you access a field or method through a pointer, Go silently inserts `*`

```
type Person struct {
    Name string
    Age  int
}
p := &Person{Name: "Alice", Age: 30}
// You write:       p.Age++
// Go compiles it:  (*p).Age++
```

```
// Both are identical · Go does it for you
```

This works for **any depth of pointer**:

```
p := &Person{Age: 30}
pp := &p   // pointer to a pointer
pp.Age++        // Go does: (*(*pp)).Age++  · all the way down
fmt.Println(pp) // still works
```

When does auto-deref happen?

· Always · whenever you use . (dot notation) on a pointer type.

```
p.Name    // · auto-deref · (*p).Name
p.Age++   // · auto-deref · (*p).Age++
p.Method() // · auto-deref if Method has value receiver
```

When must you write `*` explicitly?

· When you want the **whole value**, not a field:

```
n := new(int)
*n = 10
fmt.Println(*n)   // · must be explicit · you want the int value
fmt.Println(n)    // prints address: 0xc000018080
// Assigning the whole value:
*n = 99           // · must be explicit · replacing the entire value
n = 99            // · compile error · n is *int, not int
```

Rule of thumb: Use `*` explicitly when you're working with the **whole pointed-to value**, not a field/method inside it.

Trick 2: Auto-Address (calling pointer-receiver methods on values)

Rule: When a method requires `*T` but you have `T`, Go silently inserts `&` · BUT only if the variable is addressable

```
type Counter struct{ count int }
func (c *Counter) Increment() { c.count++ }  // pointer receiver
c := Counter{count: 0}  // c is a plain Counter (value, not
pointer)
c.Increment()     // You write this
(&c).Increment()  // Go compiles it as this · c is addressable ·
```

What is "addressable"?

A variable is addressable if Go can take its memory address with `&`.

```
// · ADDRESSABLE · auto-address works
c := Counter{}        // local variable
c.Increment()         // works · Go does (&c).Increment()
arr := [3]Counter{}
```

```
arr[0].Increment()    // works · array element is addressable
s := []Counter{{}}
s[0].Increment()      // works · slice element is addressable
// · NOT ADDRESSABLE · auto-address FAILS, must be explicit
Counter{}.Increment()                  // · compile error · temporary
value, no address
getCounter().Increment()               // · compile error · function
return value, no address
map[string]Counter{}["x"].Increment()  // · compile error · map values
are not addressable
```

The temporary `Counter{}` has no memory address because Go hasn't assigned it a location yet. There's nothing to point to.

The fix for non-addressable cases:

```
// Instead of:
Counter{}.Increment()          // ·
// Do:
c := Counter{}
c.Increment()                   // · now it has an address
// Or use a pointer from the start:
c := &Counter{}
c.Increment()                   // · already a pointer
```

The Full Decision Table

```
You have T,  method wants T  · direct call, nothing special
You have T,  method wants *T · Go auto-addresses: (&T).Method()  [if
addressable]
You have *T, method wants *T · direct call, nothing special
You have *T, method wants T  · Go auto-derefs: (*T).Method()
```

When to Write It Explicitly vs Leave It Implicit

Leave it implicit (let Go handle it):

```
// Field access · always let Go handle it
p.Name = "Alice"       // NOT (*p).Name = "Alice"
p.Age++                // NOT (*p).Age++
// Method calls on variables · always let Go handle it
c.Increment()          // NOT (&c).Increment()
p.SomeMethod()         // NOT (*p).SomeMethod()
```

Writing `(*p).Age` or `(&c).Increment()` is valid Go, but it's **noisy and unusual** · no Go developer writes it that way in practice.

Write it explicitly when:

```
// 1. You want the whole value behind a pointer
```

```
val := *p              // · copying the entire struct
fmt.Println(*n)        // · printing an int value, not its address
// 2. You're assigning to the whole pointed-to value
*n = 42                // · replacing the entire value
*p = Person{"Bob", 25} // · replacing the entire struct
// 3. You're taking an address to pass somewhere
someFunc(&x)           // · passing address of x to a function
p := &Person{}         // · creating a pointer to a new struct
// 4. Nil checks · always explicit
if p != nil {          // · checking if pointer is nil
    fmt.Println(p.Name)
}
// 5. Double pointers (rare)
pp := &p               // · pointer to a pointer
```

One Slide Summary

```
AUTO-DEREF  (p.Field, p.Method)
  · Go inserts * automatically
  · ALWAYS works on pointer types with dot notation
  · Write * explicitly only when grabbing/replacing the WHOLE value
AUTO-ADDRESS  (c.PointerMethod())
  · Go inserts & automatically
  · ONLY works when variable is ADDRESSABLE (has a memory slot)
  · Fails on: temporaries, function returns, map values
  · Write & explicitly when passing to functions or creating pointers
GOLDEN RULE:
  Use dot notation normally (p.Name, c.Increment())
  Use * only when you mean "give me everything at this address"
  Use & only when you mean "give me the address of this thing"
```

Deep Dive: Go Closures & Scopes · funcval, Capture by Reference, and the Compiler's Transformation

Everything the compiler does when you create a closure: scope resolution, variable capture, heap escape, the funcval struct, and what breaks at scale.

1. Block Scoping in Go · The Scope Chain

Go resolves variable names at **compile time** by walking a scope chain. Every `{}` creates a new lexical scope. The compiler never needs the runtime for name resolution · it's all determined before the binary is built.

The Four Scope Levels

```
.................................................................
·  UNIVERSE SCOPE  (predeclared: true, false, nil, len, cap,     ·
·                   append, make, new, error, int, string, ...)  ·
·  ..............................................................   ·
·  ·  PACKAGE SCOPE  (package-level var, const, func, type)  ·   ·
·  ·  ...................................................   ·   ·
·  ·  ·  FILE SCOPE  (import declarations only)           ·   ·   ·
·  ·  ·  ..............................................   ·   ·   ·
·  ·  ·  ·  FUNCTION SCOPE  (params, named returns)  ·   ·   ·   ·
·  ·  ·  ·  ......................................   ·   ·   ·   ·
·  ·  ·  ·  ·  BLOCK SCOPE  (if, for, switch, {}) ·   ·   ·   ·   ·
·  ·  ·  ·  ·  ...............................    ·   ·   ·   ·   ·
·  ·  ·  ·  ·  ·  NESTED BLOCK SCOPE          ·    ·   ·   ·   ·   ·
·  ·  ·  ·  ·  ...............................    ·   ·   ·   ·   ·
·  ·  ·  ·  ...................................   ·   ·   ·   ·   ·
·  ·  ·  ......................................   ·   ·   ·   ·   ·
·  ·  ..............................................   ·   ·   ·   ·
·  ..................................................   ·   ·   ·
.................................................................
```

Resolution rule: The compiler walks outward from the current scope. The first match wins. An inner variable with the same name **shadows** the outer one · the outer variable still exists but is unreachable by name within the inner scope.

Multi-Level Shadowing Trace

```
x := "package"                          // scope A
func example() {                        // scope B
    x := "function"                     // shadows A's x
    fmt.Println(x)                      // · "function"
    if true {                           // scope C
        x := "if-block"                // shadows B's x
        fmt.Println(x)                 // · "if-block"
        for i := 0; i < 1; i++ {       // scope D
            x := "for-block"           // shadows C's x
            fmt.Println(x)             // · "for-block"
        }
        fmt.Println(x)                 // · "if-block" (C's x, D is
gone)
    }
```

```
    fmt.Println(x)                    // · "function" (B's x, C is
gone)
}

Compiler's scope chain lookup for "x" inside the for-body:
   scope D: x = "for-block"  · FOUND, stop looking
   scope C: x = "if-block"       (shadowed · unreachable from D)
   scope B: x = "function"       (shadowed)
   scope A: x = "package"        (shadowed)
```

`:=` vs `var` · Both Create in Current Scope

Both `x := val` and `var x = val` declare a new variable in the **current** scope. The `:=` operator is not "reassignment" · it is always a **new declaration**. This is why `i := i` inside a loop body creates a separate variable: the right-hand `i` resolves to the outer scope, the left-hand `i` declares in the current scope.

Key insight: Shadowing is resolved entirely at compile time. There is no runtime scope chain walk. The compiler assigns each variable to a specific stack slot or heap location.

Source: `cmd/compile/internal/types2` · Go's type checker resolves all scopes at compile time.

---

2. Functions as First-Class Values · The `funcval` Struct

In Go, functions are values. They have a type (`func(params) returns`), can be assigned to variables, passed as arguments, and returned from other functions. But under the hood, a function value is not just a code pointer.

The `runtime.funcval` Struct

Every function value in Go is a pointer to a `funcval` struct. The struct's first field is always the function's code pointer.

```
runtime.funcval
.......................................
·  fn  uintptr   // pointer to the    ·
·                // machine code       ·
.......................................
```

Source: `runtime/runtime2.go`

```
type funcval struct {
    fn uintptr
    // variable-size, fn-specific data here
}
```

Simple Function Value (No Closure)

```
func add(a, b int) int { return a + b }
var f func(int, int) int = add

  Stack variable f:
  ................
  ·  f ............· funcval{fn: 0x48a230}
  ................             ·
                               ·
```

```
                                    machine code for add()
                                    at address 0x48a230
```

For a non-closure function value, the `funcval` contains only the code pointer. The compiler often places these in read-only data · they are effectively singletons. Assigning `add` to multiple variables all point to the same `funcval`.

Why a Pointer to a Struct, Not Just a Code Pointer?

The calling convention requires it. When Go calls a function through a function value, it passes the `funcval` pointer in a register (DX on amd64). For simple functions, this pointer is unused inside the function. For closures, the function reads its captured variables through this pointer. The uniform representation · always `funcval*` · means the caller doesn't need to know whether it's calling a closure or a plain function.

```
Call through function value:
  1. Load funcval pointer into DX register
  2. Load funcval.fn (code address) from [DX+0]
  3. CALL [DX+0]
  4. Inside the function: DX points to funcval · closure reads
captured vars from [DX+8], [DX+16], ...
```

---

3. Closures · The Compiler's Transformation

A closure is a function literal that references variables from its enclosing scope. The compiler transforms it into a `funcval` struct with captured variable pointers appended after the code pointer.

Source Code · Compiler Output

```
func makeAdder(x int) func(int) int {
    return func(y int) int {
        return x + y
    }
}
adder := makeAdder(5)
fmt.Println(adder(3))   // 8
```

Step 1 · Compiler Identifies Free Variables

```
Compiler scans the function literal func(y int) int { return x + y
}
  ·· "y" · declared as parameter · local, not captured
  ·· "x" · NOT declared in this function · FREE VARIABLE
  ·         resolved to makeAdder's parameter "x"
  ·· This function literal is a CLOSURE (has free variables)
```

Step 2 · Compiler Generates the Closure Struct

The compiler creates an anonymous struct type with the code pointer first, followed by pointers to each captured variable:

```
// Compiler-generated (conceptual):
type closure_makeAdder_func1 struct {
    F    uintptr    // code pointer to the anonymous function
```

```
    x    *int       // pointer to captured variable x
}
```

Step 3 · Memory Layout

```
makeAdder(5) is called:
x (heap-allocated because closure escapes):
...........
·  x = 5  · ..........................................
...........                                          .
                                                     .
Closure struct (heap-allocated · returned to caller):   ·
.......................................              .
· fn = 0x48b100      · x = 0xc00001a0b0 ...............
· (anonymous func    · (pointer to the  ·
·  code address)     ·  captured x)     ·
.......................................
Returned to caller:   adder ··· closure{fn: 0x48b100, x: ··· [5]}
```

Step 4 · Calling the Closure

```
adder(3) execution:
  1. Load funcval pointer (closure struct) into DX
  2. Load DX.fn · 0x48b100 · CALL
  3. Inside the function body:
     ·· y = 3             (normal parameter from stack/register)
     ·· x = *([DX+8])     (load pointer from closure struct,
dereference · 5)
     ·· return 5 + 3 = 8
```

Source: `cmd/compile/internal/walk` · The compiler's closure transformation happens during the walk phase. See `cmd/compile/internal/walk/closure.go`.

---

4. Capture by Reference, Not Value

This is the single most important thing to understand about Go closures: **closures capture VARIABLES, not values.** The closure struct holds a **pointer** to the variable, not a copy of its value.

Proof: Shared Variable

```
x := 10
inc := func() { x++ }
get := func() int { return x }
inc()
fmt.Println(get())   // 11 · both closures share the SAME x
inc()
fmt.Println(get())   // 12
```

Memory Layout · Two Closures, One Variable

```
Stack/Heap:
```

```
  .............
  ·   x = 12  · ............................
  .............                             .
       .                                    .
       .                                    .
  ........................    ............................
  · closure "inc"         ·    · closure "get"            ·
  · ..................... .    · .......................  .
  · · fn     · x ................. fn     · x .............
  · · inc's  · (ptr to  · ·    · · get's  · (ptr to    ·
  · · code   ·  same x) · ·    · · code   ·  same x)   ·
  · ..................... .    · .......................  .
  ........................    ............................
  Both closures hold a *int pointing to the SAME x.
  inc() modifies x through its pointer. get() reads x through its
pointer.
```

Why Pointers, Not Copies?

The Go spec says closures "may refer to variables defined in a surrounding function. Those variables are then shared." The word "shared" is key · a copy would break this contract. The compiler achieves sharing by moving captured variables to the heap (if they escape) and replacing all references · in both the enclosing function and the closure · with pointer dereferences through the same heap location.

The `i := i` Fix · Creating a New Variable

```
for i := 0; i < 3; i++ {
    i := i   // NEW variable · shadows the loop's i
    funcs[i] = func() { fmt.Println(i) }
}

  Without i := i (one shared variable):       With i := i (three
separate variables):
  funcs[0].closure.i ···                      funcs[0].closure.i ···
[i· = 0]
  funcs[1].closure.i ····· [ i = 3 ]          funcs[1].closure.i ··· [i· =
1]
  funcs[2].closure.i ···                       funcs[2].closure.i ···
[i· = 2]
  All see final value 3.                       Each sees its own
snapshot.
```

Go 1.22 Range Loop Change

Go 1.22 changed range loops so each iteration creates a **new loop variable**:

```
// Go 1.22+: range loops create a new variable per iteration
(FIXED)
for i, v := range slice {
    go func() { fmt.Println(i, v) }()   // · safe · each iteration's i,
v is unique
}
// C-style for loops are NOT changed · still one variable for the
```

```
entire loop
for i := 0; i < len(slice); i++ {
    go func() { fmt.Println(i) }()      // · STILL BROKEN · all share
one i
}
```

Source: Go proposal #60078. The compiler inserts an implicit `i := i` at the top of each range loop iteration body starting in Go 1.22.

---

5. Escape Analysis and Closures

When a closure captures a local variable, the compiler must decide: can that variable stay on the stack, or must it move to the heap? This decision is **escape analysis**, and closures are one of the most common triggers for heap escapes.

The Rule

If a closure **escapes** the function where the captured variable is declared, the captured variable MUST be heap-allocated. "Escapes" means: returned, passed to a goroutine, stored in a struct/slice/map/package-var, or sent through a channel.

Case 1 · Closure Escapes · Variable Escapes to Heap

```
func makeCounter() func() int {
    count := 0                        // count ESCAPES to heap
    return func() int {               // closure ESCAPES (returned)
        count++
        return count
    }
}

$ go build -gcflags='-m' .
./main.go:3:2: moved to heap: count
./main.go:4:9: func literal escapes to heap
```

`count` must survive beyond `makeCounter`'s stack frame, so the compiler heap-allocates it. The returned closure's funcval struct (also on heap) holds a pointer to that `count`.

Case 2 · Closure Does NOT Escape · Variable Stays on Stack

```
func process(items []int) int {
    sum := 0
    apply := func(x int) { sum += x }  // closure does NOT escape ·
sum stays on stack
    for _, item := range items { apply(item) }
    return sum
}

$ go build -gcflags='-m' .
./main.go:3:12: func literal does not escape
```

`apply` is never stored, returned, or goroutined. Everything stays on stack. **No GC pressure.**

Case 3 · Goroutine Always Escapes

```
func worker(tasks []Task) {
    for _, t := range tasks {
        t := t                  // new var per iteration (Go 1.22+
range: automatic)
        go func() { process(t) }()  // closure + t escape to heap
    }
}
```

Rule of thumb: `go func() { ... }()` always escapes. Every goroutine launch = heap allocation.

Escape Analysis Decision Tree for Closures

```
Closure is created
·· Returned from function?              · escapes · captured vars
heap-allocated
·· Passed to go func()?                 · escapes · captured vars
heap-allocated
·· Stored in struct/slice/map/pkg var?  · escapes · captured vars
heap-allocated
·· Sent through a channel?              · escapes · captured vars
heap-allocated
·· Only called within declaring func?   · does NOT escape · stack ·
```

---

6. Closures and Goroutines · Race Conditions

Launching a goroutine with `go func() { ... }()` creates a closure that captures variables by reference. If the enclosing function modifies those variables after the goroutine launches, you have a **data race**.

The Race

```
func process() {
    data := "initial"
    go func() {
        fmt.Println(data)      // READ data · when? unpredictable
    }()
    data = "modified"          // WRITE data · race with the
goroutine's read
}
```

Race Timeline

```
  Main goroutine (G1)           Spawned goroutine (G2)
  ....................          ........................
  data := "initial"
  go func() { ... }()
  ·                             (G2 scheduled · maybe now, maybe later)
  data = "modified"  ··· WRITE
  ·                             fmt.Println(data) ··· READ
  ·                             ·
  ........ RACE ................
```

```
No synchronization between WRITE and READ.
go vet / -race will flag this.
```

The Fix: Pass as Argument (Copy)

```
func process() {
    data := "initial"
    go func(d string) {        // d is a COPY of data at launch
time
        fmt.Println(d)         // reads the copy · no race
    }(data)                    // data is copied into d HERE
    data = "modified"          // only modifies original · d is
independent
}
```

Detection

```
go test -race ./...            # ALWAYS run in CI · non-negotiable
go vet ./...                   # detects common
closure-over-loop-var patterns
```

`go vet` specifically checks for `go func() { ... uses loop var ... }()` patterns and reports: `loop variable i captured by func literal`.

---

7. The Classic Gotchas

Gotcha 1 · Loop Variable Capture (C-Style For Loop)

Still broken in Go 1.22+ · the range loop fix does NOT apply to C-style `for` loops.

```
funcs := make([]func(), 3)
for i := 0; i < 3; i++ {
    funcs[i] = func() { fmt.Println(i) }   // all capture the SAME
i
}
funcs[0]()   // 3 ·
funcs[1]()   // 3 ·
funcs[2]()   // 3 ·
```

Why: One `i` variable exists for the entire loop. All closures hold `*int` pointing to that single `i`. When the loop ends, `i == 3`.

Fix: Shadow it ·`i := i` inside the body, or pass as argument.

Gotcha 2 · Deferred Closure in a Loop

```
for i := 0; i < 3; i++ {
    defer func() {
        fmt.Println(i)     // prints 3, 3, 3 (LIFO order, all see
i=3)
    }()
}
```

Defers run when the **function** returns, not when the loop iteration ends. By that time, `i` is already 3.

Fix:

```
for i := 0; i < 3; i++ {
    defer func(n int) {
        fmt.Println(n)     // prints 2, 1, 0 (LIFO order, each sees
its own n)
    }(i)
}
```

Gotcha 3 · Goroutine Closure in a Loop

```
for i := 0; i < 3; i++ {
    go func() {
        fmt.Println(i)     // race condition + wrong values
    }()
}
```

Two bugs: (a) all closures share one `i`, (b) race between `i++` and goroutine reads.

Fix:

```
for i := 0; i < 3; i++ {
    go func(n int) {
        fmt.Println(n)     // each goroutine gets its own copy
    }(i)
}
```

Gotcha 4 · Closure Capturing Mutated Outer Variable

```
func makeHandlers() []http.HandlerFunc {
    handlers := make([]http.HandlerFunc, 0)
    prefix := "/api"
    for _, version := range []string{"v1", "v2", "v3"} {
        handlers = append(handlers, func(w http.ResponseWriter, r
*http.Request) {
            fmt.Fprintf(w, "%s/%s", prefix, version)
        })
    }
    prefix = "/internal"  // ALL handlers now print "/internal/vX"
· shared by reference!
    return handlers
}
```

Fix: Snapshot `prefix` before creating closures: `p := prefix` and use `p` in closures.

Go 1.22 Gotcha Summary

```
.......................................................................
· Loop Type                          · Go · 1.21    · Go 1.22+

8. Method Values and Method Expressions

Method values are closures in disguise. When you write `p.String`, Go creates a closure that binds the receiver.

Method Value · Binds the Receiver

```
type Person struct{ Name string }
func (p Person) String() string { return p.Name }
p := Person{Name: "Alice"}
f := p.String          // method value · f is a closure
fmt.Println(f())       // "Alice"
```

Compiler Transformation

The compiler transforms `p.String` into a closure that captures a **copy** of the receiver:

```
// Compiler-generated (conceptual):
type methodValue_Person_String struct {
    F        uintptr   // code pointer to a wrapper function
    receiver Person    // COPY of p (value receiver · copied)
}
// The wrapper function:
func wrapper(mv *methodValue_Person_String) string {
    return mv.receiver.String()
}
```

Memory Layout

```
  p := Person{Name: "Alice"}
  f := p.String
  f (funcval pointer):
  ................
  ·  f ............· methodValue{
  ................      fn: wrapper_code_ptr,
                        receiver: Person{Name: "Alice"}  · COPY of p
                      }
  p.Name = "Bob"
```

```
f()   · "Alice"   // f captured a COPY · doesn't see the change
```

Key insight for value receivers: The receiver is **copied** at the time the method value is created. Later changes to `p` don't affect `f`.

Pointer Receiver · Captures the Pointer

```
func (p *Person) SetName(name string) { p.Name = name }
p := &Person{Name: "Alice"}
f := p.SetName                 // captures the POINTER
f("Bob")
fmt.Println(p.Name)            // "Bob" · f holds the same pointer
```

With pointer receivers, the method value captures the pointer itself · mutations through `f` are visible through `p` (both point to the same `Person`).

Method Expression · No Binding

```
f := Person.String              // method expression · NOT a closure
fmt.Println(f(Person{"Carol"})) // must pass receiver explicitly ·
type: func(Person) string

.......................................................................
·                      · Method Value  · Method Expression            ·
.......................................................................
· Syntax               · p.String      · Person.String                ·
· Resulting type       · func() string · func(Person) string          ·
· Is a closure?        · YES           · NO                           ·
· Receiver bound?      · YES (copied   · NO (must pass explicitly)    ·
·                      ·  or pointed)  ·                              ·
· Heap allocation?     · YES (funcval) · NO (static funcval, singleton) ·
.......................................................................
```

---

9. Common Closure Patterns in Production

Pattern 1 · Functional Options

```
type Option func(*ServerConfig)
func WithAddr(addr string) Option {
    return func(c *ServerConfig) { c.Addr = addr }  // captures
addr by reference
}
func NewServer(opts ...Option) *Server {
    cfg := ServerConfig{Addr: ":8080", ReadTimeout: 30 *
time.Second}
    for _, opt := range opts { opt(&cfg) }  // each option closure
mutates cfg
    return &Server{cfg: cfg}
}
```

Each `With*` function returns a closure capturing its argument. Short-lived, minimal GC impact.

Pattern 2 · HTTP Middleware

```
func logging(next http.Handler) http.Handler {
    return http.HandlerFunc(func(w http.ResponseWriter, r
*http.Request) {
        start := time.Now()
        next.ServeHTTP(w, r)       // closure captures 'next' from
outer scope
        slog.Info("request", "method", r.Method, "duration",
time.Since(start))
    })
}
// Usage: handler = logging(authCheck(myHandler))  · chain of
closures
```

Pattern 3 · Memoization

```
func memoize(f func(int) int) func(int) int {
    cache := make(map[int]int)     // captured by the returned
closure
    return func(n int) int {
        if v, ok := cache[n]; ok { return v }
        v := f(n)
        cache[n] = v
        return v
    }
}
```

Warning: NOT goroutine-safe. Multiple goroutines race on `cache`. Add `sync.Mutex` for concurrent use.

Pattern 4 · Deferred Cleanup

```
func withTempFile(fn func(f *os.File) error) error {
    f, err := os.CreateTemp("", "work-*")
    if err != nil { return err }
    defer func() { f.Close(); os.Remove(f.Name()) }()  // closure
captures f
    return fn(f)
}
```

The deferred closure captures `f`. Since it runs before `withTempFile` returns, `f` stays on stack (no escape). Clean resource management.

Pattern 5 · Iterator (Go 1.23+ Range-Over-Function)

```
func Filter[T any](seq iter.Seq[T], pred func(T) bool) iter.Seq[T]
{
    return func(yield func(T) bool) {
        for v := range seq {       // closure captures seq and pred
            if pred(v) && !yield(v) { return }
        }
    }
}
```

10. Performance Implications

Closure Call vs Direct Call

```
Direct call:       CALL 0x48a230       · address known at compile
time, CAN be inlined
Function value:    MOV DX, [fv_ptr]    · indirect call through
funcval.fn, CANNOT be inlined
Closure call:      MOV DX, [cl_ptr]    · indirect + captured var
loads from [DX+8], ...
```

Allocation Costs

```
.............................................................................
· Scenario                      · Heap Allocs      · Why
          ·
.............................................................................
· Non-escaping closure, no      · 0                · Closure struct +
captured vars ·
· captured vars escape          ·                  · all stay on stack
         ·
.............................................................................
· Returned closure (escapes)    · 1 + N            · 1 for funcval struct,
         ·
·                               ·                  · N for each captured
variable   ·
·                               ·                  · that must move to
heap         ·
.............................................................................
· go func() { ... }()           · 1 + N            · Goroutine closures
always      ·
· with captured vars            ·                  · escape
         ·
.............................................................................
· Method value (p.Method)       · 1                · funcval struct with
receiver   ·
·                               ·                  · copy · always
heap-allocated   ·
.............................................................................
· Method expression (T.Method)  · 0                · Static funcval ·
singleton     ·
·                               ·                  · in read-only data
         ·
.............................................................................
```

When to Avoid Closures in Hot Paths

In performance-critical inner loops (100k+ ops/sec), consider using a struct with methods:

```
// Closure version · heap alloc, not inlineable:
func makeProcessor(threshold int) func(int) bool {
```

```
    return func(v int) bool { return v > threshold }
}
// Struct version · no closure, inlineable, no heap alloc:
type Processor struct{ Threshold int }
func (p Processor) Check(v int) bool { return v > p.Threshold }
```

Verify with Escape Analysis

```
go build -gcflags='-m' ./...          # see what escapes
go build -gcflags='-m -m' ./...       # detailed reasons for each
escape decision
go test -bench=. -benchmem ./...      # measure allocations per
operation
```

---

11. Defer Internals · Under the Hood

`defer` is a closure mechanism · when you write `defer f()`, Go captures the function and its arguments for later execution. Understanding the implementation matters for performance in loops.

Three Implementations (Historical Evolution)

```
Go Version    Implementation           Cost per defer
..........    ......................   ...............
Go 1.0·1.12   Heap-allocated record    ~50ns (malloc + free)
Go 1.13       Stack-allocated record   ~35ns (no heap)
Go 1.14+      Open-coded defer         ~0ns  (compiler inlines it)
```

Open-Coded Defer (Go 1.14+ · Current)

For simple, non-loop defers, the compiler **inlines** the deferred call directly at every return point. No runtime data structure needed.

```
// What you write:
func process(f *os.File) error {
    defer f.Close()
    data := read(f)
    if err := validate(data); err != nil {
        return err       // Close() called here
    }
    return save(data)    // Close() called here too
}
// What the compiler generates (conceptual):
func process(f *os.File) error {
    data := read(f)
    if err := validate(data); err != nil {
        f.Close()        // · inlined at return point 1
        return err
    }
    result := save(data)
    f.Close()            // · inlined at return point 2
    return result
}
```

Cost: nearly zero · just a regular function call, no heap allocation, no deferecord management.

When Open-Coded Defer Does NOT Apply

The compiler falls back to the slower record-based approach when:

```
1. Defer inside a LOOP · number of defers is unknown at compile time
2. More than 8 defers in a function · exceeds the bit mask
3. Defer of a closure that captures variables · complex cleanup
needed
```

Defer in Loops · The Performance Trap

```
// · SLOW · creates a defer record per iteration (not open-coded):
func processFiles(paths []string) error {
    for _, path := range paths {
        f, err := os.Open(path)
        if err != nil { return err }
        defer f.Close()              // N defer records, all run at
function return!
    }
    // ALL files are open simultaneously until function returns
    // + N defer records consuming memory
    return nil
}
// · FAST · extract to helper function:
func processFiles(paths []string) error {
    for _, path := range paths {
        if err := processOne(path); err != nil {
            return err
        }
    }
    return nil
}
func processOne(path string) error {
    f, err := os.Open(path)
    if err != nil { return err }
    defer f.Close()     // · open-coded! Only 1 defer, runs at
processOne return
    // file is closed after each iteration, not held open
    return process(f)
}
```

Defer Execution Order · LIFO

```
func example() {
    defer fmt.Println("first")     // pushed first · runs last
    defer fmt.Println("second")    // pushed second · runs second
    defer fmt.Println("third")     // pushed last · runs first
}
// Output: third, second, first
```

Defer Argument Evaluation · At Defer Time, Not Call Time

```
func example() {
    x := 10
    defer fmt.Println(x)     // x is evaluated NOW · captures 10
    x = 20
}
// Output: 10  (not 20!)
// But closures capture by reference:
func example2() {
    x := 10
    defer func() { fmt.Println(x) }()   // closure captures &x
    x = 20
}
// Output: 20  (closure reads x at call time)
```

---

12. Quick Reference Card

```
SCOPE CHAIN
  Universe · Package · File · Function · Block · Nested Block
  Compiler resolves innermost-first. := and var both declare in
CURRENT scope.
FUNCVAL STRUCT
  Every function value = pointer to funcval{fn uintptr, ...captured
vars}
  Simple function: singleton in rodata. Closure: fn + pointers to
captured vars.
  Calling convention: funcval pointer in DX register (amd64).
CAPTURE RULES
  Closures capture VARIABLES (pointers), not values (copies).
  Multiple closures over same variable share it · mutations visible
to all.
  Fix: i := i (shadow), or pass as function argument (copy).
GO 1.22 LOOP CHANGE
  Range loops: new variable per iteration (fixed).
  C-style for loops: ONE variable for entire loop (NOT fixed).
ESCAPE TRIGGERS
  Closure returned / goroutined / stored / sent on channel · heap
escape.
  Closure used only locally · stack. Method values always
heap-allocate.
GOROUTINE SAFETY
  go func() { uses x }()  · RACE if x modified after launch.
  go func(x T) { uses x }(x)  · safe (copy).
METHOD VALUES vs EXPRESSIONS
  p.Method · closure (binds receiver, heap)    type: func(...) ...
  T.Method · plain function value (no binding) type: func(T, ...) ...
TOOLS
  go build -gcflags='-m'        # escape analysis
  go build -gcflags='-S'        # assembly: funcval construction
  go test -race ./...           # race detector
  go vet ./...                  # loop variable capture warnings
```

One-Line Summary

A closure is a `funcval` struct `{code_ptr, &captured_var1, &captured_var2, ...}` · it captures variables by **pointer**, not by value. If the closure escapes, those variables move to the heap. This is why loop closures share one variable, why goroutine closures race, and why `i := i` fixes both.

Deep Dive: Loop Variable Capture & The Fan-In Pattern

Why closures in loops all see the same value, what the compiler does under the hood, how Go 1.22 partially fixed it, and how the fan-in pattern uses this knowledge to safely coordinate concurrent goroutines.

1. The Problem · One Address, Many Closures

Here's the classic broken code:

```
funcs := make([]func(), 5)
for i := 0; i < 5; i++ {
    funcs[i] = func() { fmt.Println(i) }
}
for _, f := range funcs { f() }
// Output: 5, 5, 5, 5, 5   · all print 5, not 0,1,2,3,4
```

Why This Happens · The Single Variable Rule

In a C-style `for` loop, Go creates **exactly one variable** `i` for the entire loop. Every closure created inside the loop captures **the address of that same** `i` · not a copy of its current value.

```
The key insight: closures capture VARIABLES (addresses), not VALUES
```

```
(copies).
```

Think of it this way: when you write `func() { fmt.Println(i) }`, the compiler does NOT snapshot `i`'s current value. Instead, it stores a **pointer to `i`**. When the closure is eventually called, it follows that pointer and reads whatever value `i` has **at that moment** · which is 5 (the value that ended the loop).

This is identical to how it works in languages you already know:

- **JavaScript (pre-`let`)**: `var i` in a `for` loop had the same bug. `let` fixed it.
- **C#**: Before C# 5.0, `foreach` had this exact behavior. Fixed in C# 5.0.
- **Python**: Same problem with closures in list comprehensions over a loop variable.

Go's version is more subtle because it looks like `i` should be scoped per iteration, but it isn't · until Go 1.22 for range loops, and **still isn't** for C-style loops.

---

2. Memory Layout · Step by Step Through the Loop

Let's trace exactly what happens in memory during the broken loop:

```
funcs := make([]func(), 5)
for i := 0; i < 5; i++ {
    funcs[i] = func() { fmt.Println(i) }
}
```

Before the Loop Starts

```
Stack frame of enclosing function:
.......................................................
·  funcs: []func()  · backing array on heap           ·
·  i:     int       · addr: 0xC000012080  value: 0    ·  · ONE variable
.......................................................
Note: i is allocated on the HEAP, not the stack. Why?
Because closures capture its address, and those closures
outlive the loop · escape analysis moves i to the heap.
```

Iteration 0: i = 0

```
Heap:
  i (0xC000012080): 0
  funcs[0] ··· funcval {
                 fn:  closure_code_ptr
                 &i:  0xC000012080      · points to the SAME i
               }
```

Iteration 1: i = 1

```
Heap:
  i (0xC000012080): 1           · value changed, address SAME
  funcs[0] ··· funcval { &i: 0xC000012080 }    · still points here
  funcs[1] ··· funcval { &i: 0xC000012080 }    · also points here
```

Iteration 2: i = 2

```
Heap:
  i (0xC000012080): 2           · value changed again, address SAME
  funcs[0] ··· funcval { &i: 0xC000012080 }    · all three
  funcs[1] ··· funcval { &i: 0xC000012080 }    · point to
  funcs[2] ··· funcval { &i: 0xC000012080 }    · same address
```

After Loop Ends (i = 5, loop condition false)

```
Heap:
  i (0xC000012080): 5           · final value after i++ makes
condition false
  funcs[0] ··· funcval { &i: 0xC000012080 }  ···
  funcs[1] ··· funcval { &i: 0xC000012080 }  ···
  funcs[2] ··· funcval { &i: 0xC000012080 }  ····· ALL point to same i
  funcs[3] ··· funcval { &i: 0xC000012080 }  ···     which now holds 5
  funcs[4] ··· funcval { &i: 0xC000012080 }  ···
  funcs[0]()  · follow pointer · read *0xC000012080 · 5
  funcs[1]()  · follow pointer · read *0xC000012080 · 5
  ...all print 5
```

The Core Visual

```
  ..................................................................
  ·                    THE BUG IN ONE PICTURE                      ·
  ·                                                                ·
  ·   ONE variable i on the heap:    [  5  ]  · addr 0xC000012080  ·
  ·                                   . . . . .                    ·
  ·                                   . . . . .                    ·
  ·   funcs[0].&i ...................... . . . .                   ·
  ·   funcs[1].&i ......................... . . .                  ·
  ·   funcs[2].&i .......................... . .                   ·
  ·   funcs[3].&i ............................ .                   ·
  ·   funcs[4].&i ..............................                   ·
  ·                                                                ·
  ·   5 closures × 1 variable = all see the same value             ·
  ..................................................................
```

---

3. What the Compiler Actually Generates

You can see the compiler's closure transformation using:

```
go build -gcflags='-m -m' ./...     # escape analysis with reasons
go build -gcflags='-S' ./...        # assembly output
```

The Broken Version · Compiler View

```
// What you write:
for i := 0; i < 5; i++ {
    funcs[i] = func() { fmt.Println(i) }
}
// What the compiler conceptually generates:
```

```
i := new(int)             // heap-allocated because closures
capture &i
*i = 0
for ; *i < 5; (*i)++ {
    funcs[*i] = &funcval{
        fn:  closure_body_ptr,
        captured_i: i,        // pointer to the SAME heap int
    }
}
// The closure body:
func closure_body(fv *funcval) {
    i := fv.captured_i        // load pointer from funcval
    fmt.Println(*i)           // dereference · reads current value of
i
}
```

Escape Analysis Output

```
$ go build -gcflags='-m' main.go
./main.go:5:6: moved to heap: i            · i escapes because
closures capture it
./main.go:6:15: func literal escapes to heap · closure stored in
slice
```

Key: The "moved to heap: i" message is your signal. If `i` didn't escape (e.g., closure only used locally), it would stay on the stack and the problem wouldn't exist · but then you wouldn't be storing closures for later use.

---

4. The Three Fixes and Their Mechanics

Fix 1: Variable Shadowing (`i := i`)

```
for i := 0; i < 5; i++ {
    i := i    // NEW variable, shadows the loop's i
    funcs[i] = func() { fmt.Println(i) }
}
```

What happens in memory:

```
Iteration 0:
  loop_i (0xC000012080): 0
  shadow_i_0 (0xC000012088): 0     · NEW heap allocation
  funcs[0].&i · 0xC000012088       · points to shadow_i_0
Iteration 1:
  loop_i (0xC000012080): 1
  shadow_i_1 (0xC000012090): 1     · ANOTHER new heap allocation
  funcs[1].&i · 0xC000012090       · points to shadow_i_1
After loop:
  loop_i: 5
  shadow_i_0: 0   · funcs[0] reads this · prints 0 ·
  shadow_i_1: 1   · funcs[1] reads this · prints 1 ·
  shadow_i_2: 2   · funcs[2] reads this · prints 2 ·
  ...
```

```
.................................................................
·                    THE FIX IN ONE PICTURE                     ·
·                                                               ·
·   FIVE separate variables on the heap:                        ·
·                                                               ·
·   shadow_i_0: [  0  ]  · funcs[0].&i points here             ·
·   shadow_i_1: [  1  ]  · funcs[1].&i points here             ·
·   shadow_i_2: [  2  ]  · funcs[2].&i points here             ·
·   shadow_i_3: [  3  ]  · funcs[3].&i points here             ·
·   shadow_i_4: [  4  ]  · funcs[4].&i points here             ·
·                                                               ·
·   5 closures × 5 variables = each sees its own value          ·
.................................................................
```

Cost: One extra heap allocation per iteration. For most code, irrelevant. In a hot path running millions of iterations, use Fix 2 instead.

Fix 2: Pass as Function Argument (Copy)

```
for i := 0; i < 5; i++ {
    funcs[i] = func(n int) func() {
        return func() { fmt.Println(n) }
    }(i)    // i is COPIED into n at call time
}
```

Or more commonly:

```
for i := 0; i < 5; i++ {
    func(n int) {
        funcs[n] = func() { fmt.Println(n) }
    }(i)
}
```

What happens: `i` is copied by value into parameter `n`. Each invocation creates a new `n` on the stack (or heap if the inner closure escapes). The closure captures `&n`, which is unique per call.

This is exactly what the `fanIn` pattern does: `go func(s <-chan int){...}(src)` copies `src` into `s` at launch time.

Fix 3: Go 1.22+ Range Loops (Automatic)

```
// Go 1.22+: range loop variables are per-iteration. No fix needed.
for i, v := range slice {
    funcs[i] = func() { fmt.Println(i, v) }   // · each closure gets
its own i, v
}
```

The compiler generates a new variable per iteration automatically. See Section 5.

---

5. Go 1.22 Range Loop Change · What the Compiler Does Differently

The Proposal

Go proposal #60078 changed the semantics of range loop variables starting in Go 1.22. This was one of the most significant language changes since Go 1.0.

Before Go 1.22 · Range Loop Compiled As:

```
// Source:
for i, v := range slice { body(i, v) }
// Compiler generated (conceptual):
{
    i := 0              // ONE i for the whole loop
    v := zero_value_T   // ONE v for the whole loop
    for ; i < len(slice); i++ {
        v = slice[i]
        body(i, v)      // all iterations share the same i, v
variables
    }
}
```

Go 1.22+ · Range Loop Compiled As:

```
// Source (same code!):
for i, v := range slice { body(i, v) }
// Compiler now generates (conceptual):
{
    for i_tmp := 0; i_tmp < len(slice); i_tmp++ {
        i := i_tmp          // NEW i per iteration
        v := slice[i_tmp]   // NEW v per iteration
        body(i, v)          // each iteration has its own variables
    }
}
```

Memory Layout Comparison

```
BEFORE Go 1.22 (range loop):
  ONE i (0xA0): 0 · 1 · 2 · 3        ONE v (0xA8): "a" · "b" · "c" · "d"
                 . . . .                             .   .   .   .
                 . . . .                             .   .   .   .
  closures all point to same address    closures all point to same
address
  · all see final value 3              · all see final value "d"
AFTER Go 1.22 (range loop):
  i_0 (0xA0): 0    v_0 (0xB0): "a"    · iteration 0 variables
  i_1 (0xA8): 1    v_1 (0xB8): "b"    · iteration 1 variables
  i_2 (0xC0): 2    v_2 (0xC8): "c"    · iteration 2 variables
  i_3 (0xD0): 3    v_3 (0xD8): "d"    · iteration 3 variables
       .                .
       .                .
  each closure          each closure
  has its own i         has its own v
```

Why Only Range Loops?

The Go team's rationale (from Russ Cox's blog post):

1. **Range loops iterate over a known collection** · the variable represents "the current element." It's natural for each iteration to have its own element.
2. **C-style `for` loops are mutation-based** · `for i := 0; i < n; i++` explicitly says "I have a variable `i`, and I mutate it." Changing this semantic would break the mental model of what `:=` and `++` mean.
3. **Backward compatibility:** The Go team analyzed all public Go code on GitHub. Range loop variable reuse caused bugs. C-style loop variable reuse rarely did (because it's less common to capture `i` from a C-style loop in a closure).

Verifying the Behavior

```
# Check your Go version's behavior:
go version
# If Go 1.22+, range loops are per-iteration by default.
# You can see what the compiler does:
GOEXPERIMENT=loopvar go build -gcflags='-m' ./...
```

---

6. C-Style For Loops · Still Broken in Go 1.25+

This is critical to remember: **even in Go 1.25.7 (your version), C-style loops are NOT fixed:**

```
// STILL BROKEN · even in Go 1.25.7:
funcs := make([]func(), 5)
for i := 0; i < 5; i++ {
    funcs[i] = func() { fmt.Println(i) }   // · all see 5
}
// STILL NEED the fix:
for i := 0; i < 5; i++ {
    i := i                                  // · shadow
    funcs[i] = func() { fmt.Println(i) }
}
```

Why This Matters in Practice

C-style loops are common when:

- Iterating with custom step sizes: `for i := 0; i < n; i += 2`
- Countdown loops: `for i := n; i >= 0; i--`
- Complex loop conditions: `for i := start; i != end; i = nextNode(i)`
- Index-based iteration where you need to skip or repeat elements

In all these cases, if you capture `i` in a closure, you must still use `i := i` or pass as a parameter.

---

7. All the Ways This Bites You

7.1 Slice of Closures (Most Common in Interviews)

```
funcs := make([]func(), 3)
```

```
for i := 0; i < 3; i++ {
    funcs[i] = func() { fmt.Println(i) }
}
// All print 3
```

7.2 Goroutines in a Loop (Most Common in Production)

```
for i := 0; i < 3; i++ {
    go func() {
        fmt.Println(i)    // race condition + wrong values
    }()
}
```

Two bugs at once:

1. All goroutines share one `i` · wrong values
2. `i++` in the loop races with goroutine reads · data race

```
$ go test -race ./...
WARNING: DATA RACE
  Write at 0xC000012080 by goroutine 1:    · the for loop's i++
  Previous read at 0xC000012080 by goroutine 7:  · the closure
reading i
```

7.3 Deferred Closures in a Loop

```
for i := 0; i < 3; i++ {
    defer func() { fmt.Println(i) }()   // all print 3 (LIFO: 3, 3,
3)
}
```

Defers run when the **enclosing function** returns, not when the iteration ends. By that time, `i` is 3.

7.4 HTTP Handlers in a Loop

```
for _, route := range routes {
    http.HandleFunc(route.Path, func(w http.ResponseWriter, r
*http.Request) {
        fmt.Fprintf(w, "Route: %s", route.Name)   // Go 1.22+: ·
fixed for range
    })
}
```

Pre-Go 1.22: All handlers would serve the last route's name. This was one of the most reported bugs in real Go web applications.

Go 1.22+: Fixed automatically for range loops.

7.5 Event Callbacks

```
buttons := []Button{...}
for i := 0; i < len(buttons); i++ {
    buttons[i].OnClick = func() {
        fmt.Printf("Clicked button %d\n", i)   // · all say last
```

```
index
    }
}
```

7.6 The Subtle Struct Field Variant

```
type Task struct {
    ID   int
    Name string
}
tasks := []Task{{1, "A"}, {2, "B"}, {3, "C"}}
var handlers []func()
// C-style loop · BROKEN even in Go 1.25+:
for i := 0; i < len(tasks); i++ {
    handlers = append(handlers, func() {
        fmt.Println(tasks[i].Name)    // · i is captured, not the
task
    })                                // panics if i == len(tasks)
at call time
}
// Range loop · FIXED in Go 1.22+:
for _, t := range tasks {
    handlers = append(handlers, func() {
        fmt.Println(t.Name)           // · t is per-iteration in Go
1.22+
    })
}
```

---

8. Production Case Study: The Fan-In Pattern · Line by Line

Now let's break down the `fanIn` function. This is a fundamental concurrency pattern that demonstrates correct closure handling in production code.

The Full Code

```
func fanIn(sources ...<-chan int) <-chan int {
    out := make(chan int)
    var wg sync.WaitGroup
    wg.Add(len(sources))
    for _, src := range sources {
        go func(s <-chan int) {
            defer wg.Done()
            for v := range s {
                out <- v
            }
        }(src)
    }
    go func() {
        wg.Wait()
        close(out)
    }()
```

```
    return out
}
```

What This Function Does · The Big Picture

```
  ............
  · source 1 ···· chan int ···
  ............               ·
  ............               ·    ...........
  · source 2 ···· chan int ·····   out   ···· chan int ··· consumer
  ............               ·    · (merged)·
  ............               ·    ...........
  · source 3 ···· chan int ···
  ............
  "Fan-In" = many input channels merged into one output channel.

  Use cases:
  - Multiple producers, one consumer
  - Aggregating results from parallel workers
  - Merging log streams from multiple services
  - Combining search results from multiple backends
```

Line-by-Line Breakdown

Line 1: `func fanIn(sources ...<-chan int) <-chan int {`

```
  sources ...<-chan int
  ··· ...           = variadic: accepts any number of arguments
  ··· <-chan int    = receive-only channel of ints
  ··· The <- before chan means: callers can ONLY READ from these
channels.
        fanIn does not need to send to them, so we restrict the type.
  <-chan int (return type)
  ··· Returns a receive-only channel. The consumer can only read from
it.
        fanIn owns the write side internally.
  Direction restriction is a COMPILE-TIME safety check:
  - If fanIn accidentally tried to send to a source: compile error
  - If the consumer accidentally tried to send to out: compile
error
```

Line 2: `out := make(chan int)`

```
  out is an UNBUFFERED channel.

  Why unbuffered?
  - Backpressure: if the consumer stops reading, the goroutines
block
      on "out <- v" instead of filling a buffer and wasting memory.
  - Simplicity: no need to guess buffer size.
  - Correctness: the consumer processes values at its own pace.
  Could use make(chan int, bufSize) for throughput optimization,
  but unbuffered is the correct default · optimize only with data.
```

```
Memory layout (from our channels session):
.....................
· hchan (on heap)   ·
·  qcount:    0     ·  · no buffer
·  dataqsiz:  0     ·
·  buf:       nil   ·  · no ring buffer allocated
·  elemsize:  8     ·  · sizeof(int)
·  closed:    0     ·
·  sendq:     nil   ·  · senders wait here
·  recvq:     nil   ·  · receivers wait here
·  lock:      0     ·
.....................
```

Lines 3-4: `var wg sync.WaitGroup` / `wg.Add(len(sources))`

```
WaitGroup is a concurrent counter:

wg.Add(3)  · counter = 3
wg.Done()  · counter-- (atomic decrement)
wg.Wait()  · blocks until counter == 0
We call Add(len(sources)) BEFORE launching goroutines · this is
critical.

.......................................................................
·  WHY Add() BEFORE the loop, not inside it?
.
·
·
·  If you do wg.Add(1) inside the loop, there's a race:
.
·
·
·    go func() { wg.Wait(); close(out) }()  // coordinator starts
.
·    for _, src := range sources {
·
·        wg.Add(1)    // · might run AFTER Wait() returns!
.
·        go func(s <-chan int) { ... }(src)
·
·    }
·
·
·
·  The Wait() goroutine could see counter==0 between iterations
.
·  and close(out) prematurely.
·
·
·
·  FIX: wg.Add(len(sources)) before ANY goroutine launches.
.
.......................................................................
```

Lines 6-12: The Worker Loop

```
for _, src := range sources {
    go func(s <-chan int) {
        defer wg.Done()
        for v := range s {
            out <- v
        }
    }(src)
}
```

Let's break this into layers:

Layer 1: The Loop Variable Capture Fix

```
  for _, src := range sources {
      go func(s <-chan int) { ... }(src)
  }
        ·           ·            ·
        ·           ·            ··· (src) = COPY src's value into s at
launch time
        ·           ··· s <-chan int = parameter, receives the copy
        ··· src = loop variable
  In Go 1.22+, range variables are per-iteration, so this would
work:
      go func() { ... use src ... }()    // · safe in Go 1.22+
  But the parameter-passing style (src · s) is STILL preferred
because:
  1. It works in ALL Go versions
  2. It's self-documenting: you can SEE the value being passed
  3. It's the convention in the Go community
  4. It works for C-style loops too (future-proof)
```

Layer 2: What Each Goroutine Does

```
  go func(s <-chan int) {       // s is this goroutine's own copy
of the channel
      defer wg.Done()           // when this goroutine exits,
decrement the counter
      for v := range s {        // read from s until s is closed
          out <- v              // forward every value to the
merged output
      }
  }(src)
  "for v := range s" desugars to:
      for {
          v, ok := <-s
          if !ok { break }     // channel closed, stop reading
          out <- v
      }
  When source channel closes · range exits · goroutine reaches end ·
  defer fires · wg.Done() · counter decrements
```

Layer 3: Memory Layout for 3 Sources

```
After the loop, 3 goroutines are running independently:
.............................................................
·  G1 (goroutine)                                           ·
·  Stack: s = sources[0]  (own copy of channel pointer)      ·
·  Running: for v := range s { out <- v }                    ·
·  defer: wg.Done()                                          ·
.............................................................
·  G2 (goroutine)                                           ·
·  Stack: s = sources[1]  (own copy of channel pointer)      ·
·  Running: for v := range s { out <- v }                    ·
·  defer: wg.Done()                                          ·
.............................................................
·  G3 (goroutine)                                           ·
·  Stack: s = sources[2]  (own copy of channel pointer)      ·
·  Running: for v := range s { out <- v }                    ·
·  defer: wg.Done()                                          ·
.............................................................

All 3 goroutines write to the SAME out channel.
The channel's internal mutex serializes concurrent sends.
Values arrive in non-deterministic order · whichever goroutine
gets scheduled first writes first.
```

Important: A channel value (`chan int`) is already a pointer to the `hchan` struct on the heap. So `s = src` copies the pointer, not the channel. Both `s` and `src` refer to the same underlying `hchan`. This is fine · channels are designed for concurrent access.

Lines 14-17: The Coordinator Goroutine

```
  go func() {
      wg.Wait()    // wait for ALL senders to finish
      close(out)   // single close point
  }()

This goroutine does TWO things:
1. wg.Wait() · blocks until ALL worker goroutines call wg.Done()
2. close(out) · signals the consumer that no more values are coming
.....................................................................
·  WHY THIS PATTERN IS ESSENTIAL
·
·
·
·  Problem: Who closes `out`?
·
·
·
·  - NOT the workers: if G1 finishes first and closes out,
·
·    G2 and G3 will panic ("send on closed channel") when they
·
·    try to send their values.
·
·
·
```

```
·  - NOT the consumer: the consumer doesn't know when all
·
·    producers are done.
·
·
·
·  - The COORDINATOR: a separate goroutine that waits for ALL
·
·    workers to finish, THEN closes the channel. This is the
·
·    only safe approach.
·
·
·
·  This is the same principle from our channels session:
·
·  "Only the sender (or coordinator) should close the channel."
·
.......................................................................
```

Why a separate goroutine for the coordinator?

```
  If we did this synchronously:
    wg.Wait()      // · BLOCKS here until all workers finish
    close(out)     // · never reached until workers done
    return out     // · never reached!
  The function would NEVER RETURN because wg.Wait() blocks.
  The consumer would never get the channel.

  By putting it in a goroutine:

    go func() { wg.Wait(); close(out) }()
    return out     // · returns immediately! Consumer can start
reading.
  The coordinator runs concurrently:
  - Consumer reads from out
  - Workers send to out
  - Coordinator waits in the background
  - When all workers finish · coordinator closes out · consumer's range
exits
```

Line 19: `return out`

```
  Returns the merged channel immediately, before any values are
produced.

  The consumer will use it like:

    merged := fanIn(ch1, ch2, ch3)
    for v := range merged {
        process(v)         // receives values from ALL sources,
interleaved
    }
    // range exits when coordinator calls close(out)
```

```
    fmt.Println("all sources exhausted")
```

9. Fan-In Execution Timeline

Here's a complete timeline showing how all the pieces interact:

```
TIME  · Main Goroutine    · G1 (src[0])      · G2 (src[1])     ·
Coordinator
.........................................................................
 t0   · fanIn(s0, s1, s2) ·                  ·                 ·
 t1   · out = make(chan)   ·                  ·                 ·
 t2   · wg.Add(3)         ·                  ·                 ·
 t3   · spawn G1, G2, G3  · start            · start           ·
 t4   · spawn coordinator ·                  ·                 · wg.Wait()
 t5   · return out         ·                  ·                 ·
(blocked,
      ·                   ·                  ·                 ·
counter=3)
.........................................................................
 t6   · consumer reads    · v=10 from s0     · (waiting for    ·
      · range merged      · out <- 10        ·  data on s1)    ·
 t7   · process(10)       ·                  · v=20 from s1    ·
      ·                   ·                  · out <- 20       ·
 t8   · process(20)       · v=11 from s0     ·                 ·
      ·                   · out <- 11        ·                 ·
.........................................................................
 t9   · process(11)       · s0 closed!       · v=21 from s1    ·
      ·                   · range exits      · out <- 21       ·
 t10  · process(21)       · wg.Done()        ·                 · counter:
3·2
      ·                   · G1 exits         ·                 ·
.........................................................................
 t11  ·                   ·                  · s1 closed!      ·
      ·                   ·                  · range exits     ·
 t12  ·                   ·                  · wg.Done()       · counter:
2·1
      ·                   ·                  · G2 exits        ·
.........................................................................
 t13  ·                   ·                  ·                 · (G3 also
done)
      ·                   ·                  ·                 · counter:
1·0
      ·                   ·                  ·                 · Wait()
returns
 t14  ·                   ·                  ·                 · close(out)
.........................................................................
 t15  · range exits       ·                  ·                 ·
Coordinator
      · (out is closed)   ·                  ·                 · exits
      · "all done!"       ·                  ·                 ·
```

The Critical Invariants

```
  1. wg.Add(N) happens BEFORE any goroutine starts     · no premature
Wait() return
  2. Each goroutine calls wg.Done() exactly ONCE        · counter
reaches exactly 0
  3. close(out) happens AFTER all goroutines finish      · no "send
on closed channel"
  4. close(out) happens exactly ONCE                     · no "close
of closed channel"
  5. return out happens BEFORE data flows                · consumer
is ready to receive
```

---

10. Fan-In Variations and Tradeoffs

Variation 1: With Context Cancellation

```
func fanIn(ctx context.Context, sources ...<-chan int) <-chan int {
    out := make(chan int)
    var wg sync.WaitGroup
    wg.Add(len(sources))
    for _, src := range sources {
        go func(s <-chan int) {
            defer wg.Done()
            for v := range s {
                select {
                case out <- v:
                case <-ctx.Done():    // stop if context cancelled
                    return            // drain stops, goroutine
exits
                }
            }
        }(src)
    }
    go func() {
        wg.Wait()
        close(out)
    }()
    return out
}
```

Why: Without context, if the consumer stops reading (crashes, timeout), the worker goroutines block forever on `out <- v` · **goroutine leak**. The `select` with `ctx.Done()` lets them exit cleanly.

Variation 2: With Buffered Output Channel

```
out := make(chan int, len(sources) * 10)    // buffer for burst
absorption
```

When: High-throughput scenarios where producer bursts shouldn't block. **Tradeoff:** Uses memory for the buffer. Values sit in buffer if consumer is slow.

Variation 3: First-Value-Wins (Fan-In with Select)

```go
// Only works for exactly 2 sources (or use reflect.Select for N)
func fanInTwo(a, b <-chan int) <-chan int {
    out := make(chan int)
    go func() {
        defer close(out)
        for a != nil || b != nil {
            select {
            case v, ok := <-a:
                if !ok { a = nil; continue }
                out <- v
            case v, ok := <-b:
                if !ok { b = nil; continue }
                out <- v
            }
        }
    }()
    return out
}
```

Tradeoff: Single goroutine instead of N, but only practical for small N. Uses `select` for multiplexing. Setting channel to `nil` disables that `select` case (a `nil` channel blocks forever in `select`).

---

11. Detection Tools

go vet · Catches Loop Capture in Goroutines

```
$ go vet ./...
./main.go:10:24: loop variable i captured by func literal
```

`go vet` specifically looks for the pattern: `go func() { ... uses loop var ... }()`

Race Detector · Catches Concurrent Access

```
$ go test -race ./...
WARNING: DATA RACE
  Write at 0x00c000012080 by goroutine 1:    · loop's i++
  Read at 0x00c000012080 by goroutine 6:     · closure reading i
```

staticcheck / golangci-lint

```
$ staticcheck ./...
SA6005: loop variable captured by closure (staticcheck)
$ golangci-lint run
main.go:10:24: G601: loop variable i captured by func literal
(gosec)
```

Escape Analysis · See What Moves to Heap

```
$ go build -gcflags='-m' main.go
./main.go:5:6: moved to heap: i          · i captured by escaping
closure
```

```
./main.go:6:15: func literal escapes     · closure stored/goroutined
```

---

12. How Other Languages Handle This

```
.......................................................................
· Language     · Behavior
   .
.......................................................................
· JavaScript   · var: shared (broken). let/const: per-iteration
(fixed).  ·
· (pre-ES6)    · Same bug! for(var i=0;...) { setTimeout(()=>log(i)) }
  .
· (ES6+)       · for(let i=0;...) creates new i per iteration. Fixed.
  .
.......................................................................
· Python       · Closures capture by name, evaluated at call time.
   .
·              · Same bug: [lambda: i for i in range(5)] · all return 4.
·
·              · Fix: [lambda i=i: i for i in range(5)] (default arg).
  .
.......................................................................
· C#           · Pre-5.0: foreach shared the variable (broken).
   .
·              · C# 5.0+: foreach creates new variable per iteration.
   .
·              · for(int i=...) still shares. Exact same split as Go!
   .
.......................................................................
· Rust         · Move semantics by default. Closures move or borrow.
   .
·              · The borrow checker prevents this bug at compile time.
   .
·              · You literally cannot have this bug in safe Rust.
   .
.......................................................................
· Java         · Lambda can only capture "effectively final" variables.
   .
·              · Loop variable is mutated · compiler rejects capture.
 .
·              · Bug is impossible, but also less flexible.
    .
.......................................................................
· Go ·1.21     · Both range and C-style: ONE variable. Both broken.
 .
· Go 1.22+     · Range: per-iteration (fixed). C-style: still ONE
(broken)·
.......................................................................
Key insight: Go 1.22's range fix mirrors C# 5.0's foreach fix. Both
languages
decided the "iteration variable" semantic was more useful than the
"mutating
```

```
counter" semantic for their foreach/range construct, while leaving
the C-style
for loop unchanged.
```

---

13. Quick Reference Card

```
LOOP CAPTURE BUG
  Closures capture VARIABLES (pointers), not VALUES (copies).
  In a loop with ONE variable, all closures share that one address.
GO VERSION BEHAVIOR
  Go ·1.21:  range AND C-style · ONE variable · BUG
  Go 1.22+:  range · per-iteration (FIXED) ·
             C-style · ONE variable (STILL BROKEN) ·
THREE FIXES
  1. Shadow:    i := i                          (new var per
iteration)
  2. Param:     go func(n int) { use(n) }(i)   (copy into
parameter)
  3. Go 1.22+:  range loops fixed automatically (C-style: still
need fix)
FAN-IN PATTERN
  Pattern: N source channels · 1 output channel
  Key rules:
    - wg.Add(N) BEFORE goroutine loop
    - Each goroutine: range source, forward to out, defer wg.Done()
    - Coordinator goroutine: wg.Wait() then close(out)
    - Pass channel as parameter: go func(s <-chan int){...}(src)
  Why coordinator?
    - Workers can't close out (other workers still sending · panic)
    - Consumer can't close out (doesn't know when producers are
done)
    - Coordinator waits for ALL workers, then safely closes
DETECTION
  go vet ./...                      # loop variable capture warnings
  go test -race ./...               # concurrent access detection
  go build -gcflags='-m' ./...      # escape analysis (heap moves)
  staticcheck ./...                 # SA6005 loop capture warning
CHANNEL DIRECTION TYPES
  chan int       · bidirectional (send and receive)
  chan<- int     · send-only (can only write to it)
  <-chan int     · receive-only (can only read from it)
  Direction is enforced at COMPILE TIME · zero runtime cost.
```

One-Line Summary

Loop closures capture the **address** of the loop variable, not its value · all closures see the final value unless you shadow (`i := i`) or copy via parameter. The fan-in pattern applies this fix to safely merge N channels through N goroutines coordinated by a WaitGroup that ensures exactly one `close()`.

Deep Dive: Go Interface Internals · iface, eface, itab & the Nil Trap

---

0. Why Interfaces? · The 6 Motivations

Before diving into runtime internals, it's essential to understand **why** interfaces exist in Go and what problems they solve. Interfaces are not just a language feature · they are the **only mechanism for abstraction and polymorphism** in Go.

Key Prerequisite: Methods Don't Require Interfaces

A struct can have methods without any interface being involved:

```
type User struct{ Name string }
func (u User) Greet() string { return "Hello, " + u.Name }
u := User{Name: "Mert"}
u.Greet() // works · no interface needed, direct call, inlineable
```

Methods belong to **types**. Interfaces define **contracts for consumers**. They are separate concepts that the compiler connects when needed.

Motivation 1: Polymorphism Without Inheritance

Go has no classes, no inheritance, no `extends`. Interfaces are the **only way** to write a function that accepts multiple types based on shared behavior:

```
func Process(r io.Reader) error {
    buf := make([]byte, 1024)
    _, err := r.Read(buf) // works for *os.File,
```

```
*http.Response.Body,
    return err            // *bytes.Buffer, *gzip.Reader,
*tls.Conn...
}
```

Without interfaces, you'd need a separate `ProcessFile()`, `ProcessHTTP()`, `ProcessBuffer()` · one per type. Interfaces let you write one function that works with any type sharing the same behavior.

Under the hood: The compiler verifies at the assignment site that the concrete type has the required methods. At runtime, the `itab` dispatches the correct method pointer. This is **structural typing** · no `implements` keyword, no registration.

Motivation 2: Decoupling · Consumer Defines the Contract

This is Go's **most important interface design decision** and the biggest departure from Java/C#. Understanding this deeply changes how you design entire systems.

The Java/C# Way: Producer Declares (Coupled)

In Java, the **producer** must know about and declare every interface it implements:

```
// The interface lives in a shared/common package
public interface UserRepository {
    User getByID(int id);
}
// The producer MUST import and declare the interface
class PostgresRepo implements UserRepository {  // · explicit
declaration
    public User getByID(int id) { ... }
}
```

The problem: `PostgresRepo` is **coupled** to `UserRepository` at compile time. If `UserRepository` adds a method, `PostgresRepo` breaks. If you want `PostgresRepo` to satisfy a new interface from a different package, you must modify `PostgresRepo`'s source code. The producer must know about every consumer upfront.

The Go Way: Consumer Defines (Decoupled)

In Go, the **consumer** defines what it needs. The producer is completely unaware:

```
// ··· package postgres (the producer) ·····................
// Knows NOTHING about any interface. Just a struct with methods.
package postgres
type UserRepo struct {
    db *sql.DB
}
func (r *UserRepo) GetByID(ctx context.Context, id int) (*User,
error) {
    // query database...
}
func (r *UserRepo) Create(ctx context.Context, u *User) error {
    // insert into database...
}
func (r *UserRepo) Delete(ctx context.Context, id int) error {
    // delete from database...
}
```

```
// ··· package service (consumer A) ···........................
// Defines ONLY what it needs · 1 method out of 3
package service
type UserReader interface {
    GetByID(ctx context.Context, id int) (*User, error)
}
func NewUserService(reader UserReader) *UserService { ... }
// ··· package admin (consumer B) ···........................
// Defines what IT needs · different subset
package admin
type UserManager interface {
    GetByID(ctx context.Context, id int) (*User, error)
    Delete(ctx context.Context, id int) error
}
func NewAdminService(mgr UserManager) *AdminService { ... }
```

Key observations:

- `postgres.UserRepo` never imports `service` or `admin` packages
- `service` only asks for `GetByID` · it can't accidentally call `Delete`
- `admin` asks for `GetByID` + `Delete` · a different, broader contract
- Both interfaces are satisfied by the **same** `*UserRepo` without it knowing
- Each consumer gets the **narrowest interface** it needs (Interface Segregation)

The Import Graph: Dependencies Point Inward

This is the architectural consequence. Compare the import graphs:

```
JAVA · dependencies point outward (producer · consumer's interface):
  ................         ......................
  ·  PostgresRepo  ··........  UserRepository     ·
  ·  (producer)    ·imports  ·  (shared interface)  ·
  ................         ......................
                                          ·
  ................                        ·
  ·  UserService   ....................
  ·  (consumer)    ·imports
  ................
GO · dependencies point inward (consumer defines what it needs):
  ................
  ·  PostgresRepo  ·  · knows nothing about anyone
  ·  (producer)    ·
  ................
          · (no import · compiler matches structurally)
          ·
  ................
  ·  UserService   ·  · defines its own UserReader interface
  ·  (consumer)    ·
  ................
```

In Go, there is **no shared interface package**. Each consumer defines exactly what it needs. The producer doesn't import the consumer. The consumer doesn't import the producer (in the interface definition · only at the wiring site in `main()`).

Why This Matters in Practice

1. You can satisfy interfaces that don't exist yet.

If someone writes a new package next year with an interface containing `GetByID`, your `postgres.UserRepo` already satisfies it · without any modification. In Java, you'd need to go back and add `implements NewInterface`.

2. Each consumer gets the minimal contract (Interface Segregation).

In Java, if `UserRepository` has 10 methods, every consumer sees all 10 · even **if** only uses 1. In Go, each consumer defines a 1-2 method interface with just what it needs. This makes code easier to understand, test, and refactor.

3. No "shared interface" package that everything depends on.

In Java/C# enterprise projects, you often see a `common` or `contracts` package that every module imports. Change one interface there · rebuild everything. In Go, each consumer's interface is local and independent · changing one doesn't affect others.

4. Swapping implementations requires zero changes in business logic.

```
// main.go · the composition root, the ONLY place that knows concrete
types
func main() {
    var repo service.UserReader
    if cfg.UseCache {
        repo = redis.NewCachedRepo(postgres.NewUserRepo(db))  //
stacked!
    } else {
        repo = postgres.NewUserRepo(db)
    }
    svc := service.NewUserService(repo)  // service doesn't care
which one
}
```

The `service` package never changes. It doesn't know Redis exists. It doesn't know PostgreSQL exists. It only knows `UserReader` · an interface it defined itself.

The Go Proverb

> *"Accept interfaces, return concrete types."*

This means:

- **Function parameters**: use interfaces (accept any type with matching behavior)
- **Function return values**: return the concrete type (give the caller full access)

```
// · Idiomatic Go
func NewUserService(store UserReader) *UserService { ... }
//                  ^^^^^^^^^^^         ^^^^^^^^^^^
//                  interface (input)   concrete (output)
// · Over-abstracted
func NewUserService(store UserReader) UserServiceInterface { ... }
//                                    ^^^^^^^^^^^^^^^^^^^^
//                  returning an interface hides the concrete type
unnecessarily
```

Return concrete types so callers can access all methods, not just the interface subset. Let the **next consumer** decide what interface to narrow it down to.

Comparison Table

| Aspect | Java/C# (Producer Declares) | Go (Consumer Defines) | |--------|---------------------------|---------------------|
| Who defines the interface? | Shared package or the producer | The consumer, locally | | Producer imports interface? | Yes · must declare `implements` | No · unaware of any interface | | Adding a method to interface | Breaks all producers | Only affects consumers who defined it | | Satisfying a new interface | Modify producer source code | Automatic · if methods match, it works | | Shared interface package | Common pattern (`contracts`, `api`) | Not needed · no shared dependency | | Minimal contracts per consumer | Hard · everyone sees the full interface | Natural · each consumer defines just what it needs |

Motivation 3: Testability

This follows directly from Motivation 2. When a function depends on an interface, you can inject a test double with zero frameworks:

```
// Production
func NewService(store UserStore) *Service { ... }
// Test · 10 lines, no mocking library
type fakeStore struct {
    users map[int]*User
}
func (f *fakeStore) GetByID(_ context.Context, id int) (*User,
error) {
    u, ok := f.users[id]
    if !ok {
        return nil, ErrNotFound
    }
    return u, nil
}
func TestService(t *testing.T) {
    svc := NewService(&fakeStore{users: map[int]*User{1: {Name:
"Mert"}}})
    // test svc methods...
}
```

Without the interface, `NewService` would take `*sql.DB` or `*PostgresRepo` · and your unit tests would need a real database.

Motivation 4: Stdlib Integration Points

The standard library defines **small interfaces as extension hooks**. Implement them and the entire Go ecosystem works with your type automatically:

| Interface | Method(s) | What You Unlock | |----------|----------|----------------| | `fmt.Stringer` | `String() string` | Custom output in `fmt.Println`, `%v`, `%s` | | `error` | `Error() string` | Entire error handling ecosystem (`errors.Is`, `errors.As`, `%w`) | | `io.Reader` | `Read([]byte) (int, error)` | Every I/O function: `bufio`, `gzip`, `json.Decoder`, `io.Copy` | | `io.Writer` | `Write([]byte) (int, error)` | `fmt.Fprintf`, `json.Encoder`, `http.ResponseWriter` | | `sort.Interface` | `Len`, `Less`, `Swap` | `sort.Sort()` for any collection | | `json.Marshaler` | `MarshalJSON() ([]byte, error)` | Custom JSON encoding | | `json.Unmarshaler` | `UnmarshalJSON([]byte) error` | Custom JSON decoding | | `http.Handler` | `ServeHTTP(w, r)` | HTTP server routing, middleware | | `encoding.TextMarshaler` | `MarshalText() ([]byte, error)` | Used as map keys in JSON, YAML, etc. |

Key insight: `Error()` and `String()` are **not special built-in methods**. They are ordinary methods that satisfy

ordinary interfaces (`error` and `fmt.Stringer`). The "magic" is that `fmt.Println` internally does a type assertion to `Stringer` · if your type satisfies it, the custom output is used. No registration, no annotation.

Your type can satisfy interfaces it has never heard of. If someone writes a new interface tomorrow with a `String() string` method, your type already satisfies it · without changing a single line of your code. This is implicit satisfaction in action.

Motivation 5: Behavioral Abstraction at Architecture Boundaries

In a production service, code is organized into **layers**. Each layer has a single responsibility. The critical question is: **how do layers talk to each other?**

The Problem: Without Interfaces, Layers Are Welded Together

Imagine a simple order service with no interfaces:

```
// ··· handler layer ···........................
package handler
import "myapp/internal/service"  // · imports concrete service
import "myapp/internal/postgres" // · imports concrete repo
(indirectly, through service)
func CreateOrder(w http.ResponseWriter, r *http.Request) {
    svc := service.OrderService{Repo: &postgres.OrderRepo{DB: db}}
    //                                ^^^^^^^^^^^^^^^^
    //     handler knows about postgres! If we switch to MongoDB,
    //     handler code changes too.
    svc.Create(order)
}
// ··· service layer ···........................
package service
import "myapp/internal/postgres"  // · welded to postgres
type OrderService struct {
    Repo *postgres.OrderRepo  // · concrete type, not an interface
}
func (s *OrderService) Create(o Order) error {
    return s.Repo.Insert(o)  // directly calls postgres
}
```

What's wrong here:

- `service` imports `postgres` · business logic is coupled to infrastructure
- Changing the database means modifying `service` AND `handler`
- You can't test `service` without a running PostgreSQL instance
- Every package knows about every other package · a dependency web

The Solution: Interfaces as Seams Between Layers

Each layer defines an interface for what it **needs from the layer below**. Each layer **never imports** the layer below · only the interface it defined:

```
// ··· domain layer (innermost · no dependencies) ···........
package domain
type Order struct {
    ID     string
    UserID string
```

```
    Amount float64
    Status string
}
// ··· service layer (defines what it needs from persistence) ·
package service
// The service defines this interface · NOT the repo package
type OrderRepository interface {
    Insert(ctx context.Context, o *domain.Order) error
    GetByID(ctx context.Context, id string) (*domain.Order, error)
    UpdateStatus(ctx context.Context, id, status string) error
}
// The service also defines this · what it needs from payment
type PaymentGateway interface {
    Charge(ctx context.Context, userID string, amount float64)
(txID string, err error)
}
type OrderService struct {
    repo    OrderRepository  // interface · doesn't know if it's
Postgres, Mongo, or a mock
    payment PaymentGateway   // interface · doesn't know if it's
Stripe, PayPal, or a mock
}
func NewOrderService(repo OrderRepository, pay PaymentGateway)
*OrderService {
    return &OrderService{repo: repo, payment: pay}
}
func (s *OrderService) PlaceOrder(ctx context.Context, o
*domain.Order) error {
    txID, err := s.payment.Charge(ctx, o.UserID, o.Amount)
    if err != nil {
        return fmt.Errorf("payment failed: %w", err)
    }
    o.Status = "paid"
    if err := s.repo.Insert(ctx, o); err != nil {
        // In production: refund the payment here
        return fmt.Errorf("save order: %w", err)
    }
    return nil
}
// ··· postgres package (implements OrderRepository) ·····
package postgres
// Knows NOTHING about the service package or its interface.
// Just a struct with methods that happen to match.
type OrderRepo struct {
    db *sql.DB
}
func (r *OrderRepo) Insert(ctx context.Context, o *domain.Order)
error {
    _, err := r.db.ExecContext(ctx,
        "INSERT INTO orders (id, user_id, amount, status) VALUES
($1,$2,$3,$4)",
        o.ID, o.UserID, o.Amount, o.Status)
    return err
}
```

```
func (r *OrderRepo) GetByID(ctx context.Context, id string)
(*domain.Order, error) { ... }
func (r *OrderRepo) UpdateStatus(ctx context.Context, id, status
string) error { ... }
// ··· stripe package (implements PaymentGateway) ···********··
package stripe
// Also knows NOTHING about the service package.
type Client struct {
    apiKey string
}
func (c *Client) Charge(ctx context.Context, userID string, amount
float64) (string, error) {
    // call Stripe API...
    return txID, nil
}
```

The Import Graph: Clean Layer Separation

```
                        ..............
                        ·   domain   ·  · no imports (pure business entities)
                        ..............
                              ·
                              · imports domain only
                        ..............
                        ·  service   ·  · defines interfaces, contains
business logic
                        ·            ·     does NOT import postgres or
stripe
                        ..............
                              ·
              ................................
              ·               ·               ·
        .............  ..............  ..............
        ·  postgres  ·  ·   stripe   ·  ·   handler   ·
        · (repo impl)·  ·(pay impl)  ·  · (HTTP layer)·
        .............  ..............  ..............
              ·               ·               ·
              ................................
                              · all wired together in
                        ..............
                        ·   main()   ·  · the composition root
                        ..............
```

Notice: `service` has **zero imports** from infrastructure packages. The arrows point **inward** · outer layers depend on inner layers, never the reverse. This is the **Dependency Inversion Principle** · and in Go, it happens naturally through consumer-defined interfaces without any DI framework.

The Composition Root: `main()` Wires Everything

`main()` is the **only place** in the entire codebase that knows all concrete types:

```
func main() {
    // --- infrastructure ---
    db, _ := sql.Open("postgres", cfg.DatabaseURL)
    repo := postgres.NewOrderRepo(db)
```

```
    pay := stripe.NewClient(cfg.StripeKey)
    // --- business logic ---
    svc := service.NewOrderService(repo, pay)
    //                              ^^^^  ^^^
    //     *postgres.OrderRepo satisfies service.OrderRepository ·
    //     *stripe.Client satisfies service.PaymentGateway ·
    //     compiler checks this HERE, at the wiring site
    // --- transport layer ---
    h := handler.NewOrderHandler(svc)
    http.ListenAndServe(":8080", h)
}
```

No DI container. No annotations. No reflection. Explicit constructor injection. If the types don't match, you get a **compile-time error** right here in `main()`.

What This Enables in Practice

1. Swap infrastructure without touching business logic.

Migrating from PostgreSQL to MongoDB? Write a new `mongo.OrderRepo` with the same methods. Change one line in `main()`. The `service` package never changes:

```
// Before
repo := postgres.NewOrderRepo(db)
// After
repo := mongo.NewOrderRepo(client)
// service.NewOrderService(repo, pay) · unchanged, doesn't care
```

2. Test business logic in complete isolation.

```
func TestPlaceOrder(t *testing.T) {
    // Fake repo · 5 lines, no database
    fakeRepo := &fakeOrderRepo{
        insertFn: func(ctx context.Context, o *domain.Order) error
{
            return nil
        },
    }
    // Fake payment · 5 lines, no Stripe
    fakePay := &fakePayment{
        chargeFn: func(ctx context.Context, uid string, amt
float64) (string, error) {
            return "tx-123", nil
        },
    }
    svc := service.NewOrderService(fakeRepo, fakePay)
    err := svc.PlaceOrder(ctx, &domain.Order{Amount: 99.99})
    if err != nil {
        t.Fatal(err)
    }
}
```

Tests run in milliseconds. No database. No network. No Stripe sandbox.

3. Teams work on layers independently.

- **Team A** works on the `postgres` package · implements new query optimizations

- **Team B** works on the `service` package · adds new business rules
- Neither team touches the other's code. The interface is the contract between them.
- As long as `postgres.OrderRepo` still has the matching methods, everything compiles.

4. Feature flags and gradual migrations.

```
func main() {
    var repo service.OrderRepository
    if cfg.UseNewDB {
        repo = cockroachdb.NewOrderRepo(newDB)  // new
implementation
    } else {
        repo = postgres.NewOrderRepo(oldDB)     // old
implementation
    }
    svc := service.NewOrderService(repo, pay)   // service is
unaware
}
```

Route 5% of traffic to CockroachDB, 95% to PostgreSQL. The service layer has **no idea** this is happening. The interface makes both implementations interchangeable.

5. Observability wrappers without modifying business logic.

```
// A logging wrapper that satisfies the same interface
type loggingRepo struct {
    next   service.OrderRepository  // wraps the real repo via
interface
    logger *slog.Logger
}
func (r *loggingRepo) Insert(ctx context.Context, o *domain.Order)
error {
    start := time.Now()
    err := r.next.Insert(ctx, o)  // delegate to real repo
    r.logger.Info("repo.Insert", "duration", time.Since(start),
"err", err)
    return err
}
// In main() · wrap the real repo
repo := postgres.NewOrderRepo(db)
loggingRepo := &loggingRepo{next: repo, logger: logger}
svc := service.NewOrderService(loggingRepo, pay)  // service sees
the same interface
```

No modifications to `postgres.OrderRepo`. No modifications to `service.OrderService`. You added observability by stacking a wrapper · this is Motivation 6 (decoration) working together with Motivation 5 (architecture boundaries).

The Layered Architecture Summary

Layer	Defines	Imports	Knows About
`domain`	Entities, value objects	Nothing	Nothing
`service`	Business logic + interfaces for dependencies	`domain` only	What behavior it needs, not who provides it
`postgres`	Repository implementation	`domain` + `database/sql`	How to store entities, not who uses them
`stripe`	Payment implementation	`domain` + Stripe SDK	How to charge, not who calls it
`handler`	HTTP transport	`domain` + `service`	How to parse requests, not how business works
`main()`	Wiring	Everything	All concrete types · the only place that does

Why This Needs Interfaces (Not Just Structs)

If `OrderService` held `*postgres.OrderRepo` (a concrete type) instead of `OrderRepository` (an interface):

- `service` would import `postgres` · coupled to infrastructure
- Testing requires a real database · slow, flaky tests
- Swapping to MongoDB · changes `service` package · changes `handler` package · ripple
- No logging wrapper possible without modifying `postgres.OrderRepo`
- Feature flags for gradual migration · impossible without `if/else` in service code

The interface is the **architectural boundary**. Without it, the layers collapse into a monolithic dependency chain.

Motivation 6: Composition Through Decoration (Wrapper Pattern)

Interfaces enable **stacking behavior in layers** · the decorator pattern. Each wrapper adds one capability and delegates everything else to the inner interface.

The `context.Context` example:

```
ctx := context.Background()                        // emptyCtx · does
nothing
ctx  = context.WithValue(ctx, "userID", 42)        // valueCtx
wraps emptyCtx
ctx  = context.WithCancel(ctx)                     // cancelCtx
wraps valueCtx
ctx  = context.WithValue(ctx, "traceID", "abc")    // valueCtx
wraps cancelCtx
```

Each wrapper struct holds the parent as the `Context` **interface**, not as a concrete type:

```
type cancelCtx struct {
    Context             // · parent as INTERFACE
    done    chan struct{}
    err     error
}
```

It only overrides the methods it cares about (`Done()`, `Err()`). Everything else (`Deadline()`, `Value()`) delegates to the parent via the embedded interface.

The same pattern in `io.Reader`:

```
file, _ := os.Open("data.gz")        // *os.File       · io.Reader
buf := bufio.NewReader(file)           // bufio.Reader   · wraps
io.Reader
gz, _ := gzip.NewReader(buf)           // gzip.Reader    · wraps
io.Reader
limited := io.LimitReader(gz, 1024)    // LimitedReader  · wraps
io.Reader
```

The same pattern in `http.Handler` middleware:

```
handler := myHandler{}                 // implements http.Handler
handler = loggingMiddleware(handler)    // wraps http.Handler ·
returns http.Handler
handler = authMiddleware(handler)       // wraps http.Handler ·
returns http.Handler
```

Why this requires an interface: If the parent field were a concrete type (e.g., `*cancelCtx`), you couldn't wrap a `valueCtx` inside a `timerCtx` inside a `cancelCtx`. The interface makes the layers **infinitely composable** · each wrapper doesn't know or care what's inside it.

> See 12_context_interface_deep_dive.md for a complete walkthrough of how `context.Context` uses this pattern.

When NOT to Use Interfaces

Equally important · interfaces have costs. Don't use them reflexively:

Anti-Pattern	Why It's Wrong
Preemptive interfaces · creating an interface before you have 2+ consumers	You're guessing at the contract. Wait until a real second use case appears
Fat interfaces · 8+ methods	*"The bigger the interface, the weaker the abstraction."* Likely a concrete type in disguise
Interfaces in hot paths · tight loops, high-frequency calls	Interface method calls go through `itab` indirection · **not inlineable** by the compiler
Interfaces for the sake of "clean code"	If there's only one implementation and you don't need testability, a concrete type is simpler and faster
Using `interface{}` / `any` everywhere	You lose type safety. Generics (Go 1.18+) solve most cases where `any` was previously needed

The rule: Create an interface when you need **polymorphism, testability, or composability**. If you're reaching for an interface with one implementation that you don't need to test in isolation · you don't need an interface.

Summary Table

#	Motivation	Core Benefit	Key Example
1	Polymorphism without inheritance	One function, many types	`io.Reader` accepted everywhere
2	Consumer-defined contracts	Dependencies point inward, packages decoupled	Service defines `UserStore`, doesn't import repo
3	Testability	Inject fakes without frameworks	10-line fake struct in test file
4	Stdlib integration hooks	Implement a method, unlock an ecosystem	`Error()` · error handling, `String()` · printing
5	Architecture boundary abstraction	Layers separated, swappable, independently deployable	Handler · Service · Repository pattern
6	Composition through decoration	Stack behaviors in layers, infinitely composable	`context.Context`, `io.Reader` chains, HTTP middleware

---

*Now that we understand **why** interfaces exist, the following sections explain **how they work under the hood** at the runtime level.*

---

1. The Two Runtime Structs: `iface` and `eface`

Go uses **two different structs** for interface values at runtime, depending on whether the interface has methods or not.

`iface` · Non-Empty Interfaces (has methods)

Used for interfaces like `io.Reader`, `fmt.Stringer`, `error`, or any custom interface with at least one method.

```
runtime.iface (16 bytes on 64-bit)
...............................................
·  tab  *itab          ·  data unsafe.Pointer ·
·  (method dispatch    ·  (pointer to the     ·
·   table + type info) ·   concrete value)    ·
...............................................
```

- `tab` · pointer to an `itab` struct (see Section 2). Contains type metadata AND a cached array of method function pointers for this specific (interface, concrete type) pair.
- `data` · pointer to the actual value. If you assigned `&User{Name: "Bob"}`, this points to that `User` on the heap.

Source: `runtime/runtime2.go`

```
type iface struct {
    tab  *itab
    data unsafe.Pointer
}
```

`eface` · Empty Interface (`interface{}` / `any`)

Used when the interface has **zero methods**. Since there's no method table needed, Go uses a simpler, lighter struct.

```
runtime.eface (16 bytes on 64-bit)
...............................................
·  _type  *_type       ·  data unsafe.Pointer ·
·  (type descriptor    ·  (pointer to the     ·
·   only, no methods)  ·   concrete value)    ·
...............................................
```

- `_type` · pointer to a `type` struct (type descriptor: size, kind, hash, GC bitmap). No method table · just "what type is this?"
- `data` · same as `iface`, points to the actual value.

Source: `runtime/runtime2.go`

```
type eface struct {
    _type *_type
    data  unsafe.Pointer
}
```

Visual Comparison

```
  Non-empty interface (e.g., io.Writer)       Empty interface
(interface{} / any)
  ......................................      ................................
  ...................                         ...................
  ·  tab ····· itab·                          · _type ····· _type struct
  ·        ·  {     ·                         ·        ·   {size, kind,
  ·        ·   inter· ·· interface type info   ·        ·    hash, gcdata}
  ·        ·   _type· ·· concrete type info    ·        ·
  ·        ·   fun[]· ·· method pointers      ·        ·
  ·        ·  }     ·                         ·        ·
  ...................                         ...................
  · data ····· concrete value on heap         · data ····· concrete value on
heap
  ...................                         ...................
```

Key insight: Both are exactly 16 bytes (two pointers). The difference is what the first pointer points TO · an `itab` (with methods) vs a bare `_type` (no methods).

2. The `itab` · The Method Dispatch Table

The `itab` is the heart of interface method dispatch. It answers: "For this specific (interface type, concrete type) pair, where are the method implementations?"

```
runtime.itab
.............................................................
·  inter  *interfacetype    // describes the interface        ·
·         {                                                   ·
·           typ    _type    // interface's own type info       ·
·           pkgpath *string // package path                   ·
·           mhdr   []imethod // list of methods the           ·
·                            // interface requires             ·
·         }                                                   ·
.............................................................
·  _type  *_type            // describes the concrete type    ·
·         {                                                   ·
·           size    uintptr   // how many bytes                ·
·           kind    uint8     // struct? ptr? int? etc.        ·
·           hash    uint32    // for fast type comparison      ·
·           str     nameOff   // type name                     ·
·           ...               // GC bitmap, alignment, etc.    ·
·         }                                                   ·
.............................................................
·  hash   uint32            // copy of _type.hash for fast    ·
·                           // type switch lookups            ·
.............................................................
·  fun    [1]uintptr        // VARIABLE SIZE array of method  ·
·         fun[0] = &(*EmailNotifier).Notify                   ·
·         fun[1] = &(*EmailNotifier).OtherMethod              ·
·         ...one entry per interface method, in sorted order  ·
.............................................................
```

How `itab` Gets Built and Cached

The runtime maintains a **global hash table** called `runtime.itabTable`.

```
                        itabTable (global, process-wide)
                        ................................
                        hash key = hash(inter, _type)
 ..............................................................
 · (io.Writer, *os.File)       · itab{ fun: [Write] }          ·
 · (io.Reader, *bytes.Buffer)  · itab{ fun: [Read] }           ·
 · (Notifier, *EmailNotifier)  · itab{ fun: [Notify] }         ·
 · (fmt.Stringer, *User)       · itab{ fun: [String] }         ·
 · ...                                                          ·
 ..............................................................
```

Lifecycle:

1. **First assignment** of `*EmailNotifier` to `Notifier` · runtime calls `runtime.getitab()`
2. `getitab()` checks `itabTable` for key `(Notifier, *EmailNotifier)`

3 **Cache miss** · runtime builds the `itab`:

- Walks the interface's method list (`inter.mhdr`)
- Walks the concrete type's method list (`_type.methods`)
- Both are sorted alphabetically · matched with a **single O(n+m) merge walk**
- Stores each matched method's function pointer in `fun[]`

4 **Stores** the new `itab` in `itabTable`
5 **All future assignments** of `*EmailNotifier` to `Notifier` · cache hit · O(1) lookup

Important: The `itab` is built **once per (interface, concrete type) pair** for the entire lifetime of the process. It's never rebuilt or garbage collected.

---

3. Compile Time vs Runtime · Who Does What?

There is no `compileTime.iface`. The compiler and runtime have distinct, complementary roles:

```
.......................................................................
·                           COMPILE TIME
    .
·  (go build · the compiler, cmd/compile)
 .
·
    .
·  1. TYPE CHECKING
    .
·     Verifies your concrete type has ALL methods the interface
requires. ·
·     If *EmailNotifier is missing Notify(), you get a compile error.
    .
·     This happens at the assignment site:
    .
·       var n Notifier = &EmailNotifier{}  // compiler checks here
   .
·
    .
·  2. CODE GENERATION
    .
·     Emits assembly instructions to:
    .
·     - Call runtime.getitab() to get/build the itab at runtime
    .
·     - Construct the iface struct {tab, data}
    .
·     - For method calls: load tab · load fun[i] · indirect CALL
·
·
    .
·  3. ESCAPE ANALYSIS
    .
·     Determines if the concrete value must escape to heap.
    .
·     Assigning to an interface almost always forces a heap
allocation    ·
```

```
·     because iface.data is an unsafe.Pointer (must outlive the
stack).   ·
·
    .
·  4. STATIC ITAB OPTIMIZATION (link time)
    .
·     For statically known assignments, the linker can pre-build some
    .
·     itab entries · avoiding the runtime.getitab() call entirely.
  .
.......................................................................
·                           RUNTIME
    .
·  (the running binary · runtime package)
 .
·
    .
·  1. ITAB TABLE
    .
·     Global hash table of cached itab entries.
    .
·     Built lazily on first use of each (interface, type) pair.
    .
·
    .
·  2. METHOD DISPATCH
    .
·     Indirect function call through itab.fun[i].
    .
·     CPU loads the function pointer and CALLs it.
    .
·
    .
·  3. TYPE ASSERTIONS / TYPE SWITCHES
    .
·     Compares itab._type.hash against target type hash.
    .
·     Fast path: hash match · verify · extract data.
·
·
    .
·  4. INTERFACE EQUALITY
    .
·     i == nil checks: tab == nil AND data == nil.
    .
·     i == j checks: same itab + deep-equal data.
   .
.......................................................................
```

Verification tools:

```
go build -gcflags='-m'     # escape analysis · what escapes to heap
go build -gcflags='-m -m'  # verbose escape analysis with reasons
go build -gcflags='-S'     # assembly output · see iface construction
```

```
& dispatch
```

---

4. Step-by-Step: Interface Assignment

Let's trace exactly what happens when you write:

```
type Notifier interface {
    Notify(msg string) error
}
type EmailNotifier struct{ smtp string }
func (e *EmailNotifier) Notify(msg string) error { /* ... */ }
var n Notifier = &EmailNotifier{smtp: "mx.google.com"}
```

Step 1 · Compile Time: Type Check

```
Compiler sees: var n Notifier = &EmailNotifier{...}
  Does *EmailNotifier have Notify(string) error?
  ·· Scan *EmailNotifier's method set
  ·· Found: func (e *EmailNotifier) Notify(msg string) error  ·
  ·· Type check passes · code generation proceeds
```

Step 2 · Compile Time: Escape Analysis

```
Compiler decides: &EmailNotifier{smtp: "mx.google.com"}
  ·· This value is assigned to an interface (iface.data =
unsafe.Pointer)
  ·· unsafe.Pointer could escape the current stack frame
  ·· Decision: ALLOCATE ON HEAP · this is the cost of interfaces
```

Step 3 · Runtime: Allocate the Value

```
  Heap:
  ...............................
  · EmailNotifier{               ·
  ·   smtp: "mx.google.com"     ·  ··· 0xc0000a4000 (heap address)
  · }                            ·
  ...............................
```

Step 4 · Runtime: Get or Build the `itab`

```
  runtime.getitab(Notifier, *EmailNotifier)
  ·· Hash lookup in itabTable
  ·· First time? Cache miss · BUILD:
  ·   ·· Walk Notifier.methods: [Notify(string) error]
  ·   ·· Walk (*EmailNotifier).methods: [Notify(string) error]
  ·   ·· Match: fun[0] = address of (*EmailNotifier).Notify
  ·   ·· Store in itabTable
  ·· Return: *itab at 0x4a7b20
```

Step 5 · Runtime: Assemble the `iface`

```
n (on the stack):
...............................................
· tab = 0x4a7b20       · data = 0xc0000a4000  ·
· (itab for            · (heap-allocated      ·
·  Notifier,           ·  EmailNotifier)      ·
·  *EmailNotifier)     ·                      ·
...............................................
          ·                      ·
          ·                      ·
    itab{                   EmailNotifier{
      inter: Notifier         smtp: "mx.google.com"
      _type: *EmailNotifier }
      fun[0]: 0x4823a0  ··· (*EmailNotifier).Notify
    }
```

---

5. Step-by-Step: Interface Method Call

Now let's trace `n.Notify("server down")`:

```
n.Notify("server down")
```

Step 1 · Load the `itab`

```
CPU reads n.tab · 0x4a7b20 (pointer to itab)
```

Step 2 · Load the Method Pointer

```
  CPU reads itab.fun[0] · 0x4823a0 (address of
(*EmailNotifier).Notify)
  fun[] index is determined at COMPILE TIME · the compiler knows
Notify is
  method #0 in the interface's sorted method list. This is a
constant offset.
```

Step 3 · Load the Data Pointer

```
CPU reads n.data · 0xc0000a4000 (pointer to EmailNotifier value)
```

Step 4 · Indirect Call

```
CALL 0x4823a0(0xc0000a4000, "server down")
     ·              ·              ·
     ·              ·              ·· argument
     ·              ·· receiver (e *EmailNotifier)
     ·· (*EmailNotifier).Notify function address
This is an INDIRECT call · the CPU doesn't know the target until it
reads the function pointer from the itab. This means:
·· The compiler CANNOT inline this call
·· The CPU branch predictor may mispredict on first call
·· Subsequent calls to the same (interface, type) pair are
```

```
predicted correctly
```

Visual Summary: The Full Call Chain

```
n.Notify("server down")
···· n ·····------------
· tab ··· itab     ·     ·· EmailNotifier ··
· data ··------------------ smtp: "mx..."   ·
·------------------------     ------------------
         ·                        ·
         ·                        ·
   itab.fun[0] ··· (*EmailNotifier).Notify(receiver, "server down")
                                  ·              ·
                                  ----------------
                                  receiver = n.data
```

---

6. The Three States of an Interface

Every interface value is in one of exactly three states:

```
var s Stringer         // State 1: (nil, nil)
s = User{Name: "Bob"}  // State 2: (*itab, 0xc000...)
var u *User
s = u                  // State 3: (*itab, nil)   · THE TRAP
```

State 1 · True Nil Interface

```
var s Stringer
s:
------------------------------
·     nil      ·     nil      ·
------------------------------
s == nil · TRUE ·   (both words are zero)
```

Both `tab` and `data` are zero. This is what `nil` means for an interface.

State 2 · Normal, Non-Nil Interface

```
s = User{Name: "Bob", Age: 25}
s:
------------------------------
·  *itab(User) ·  0xc000a080  ···· User{Name:"Bob", Age:25}
------------------------------
s == nil  · FALSE ·
s.String() · works fine ·
```

State 3 · The Nil Pointer Trap ··

```
var u *User   // u is nil
s = u         // assign nil pointer to interface
```

```
s:
.............................
·  *itab(User) ·     nil      ·
.............................
s == nil    · FALSE ·  (tab is NOT nil · it has type info!)
s.String()  · PANIC ·  (data IS nil · method dereferences nil receiver)
```

---

7. The Nil Interface Trap

Why Does This Happen?

When Go assigns a value to an interface, it **always** writes the type into the `tab` field · **regardless of whether the value itself is nil**.

```
var u *User   // concrete nil pointer · the type (*User) IS known
s = u         // Go writes: tab = itab(*User), data = nil
              // it has no way to "forget" the type just because
the value is nil
```

Go cannot collapse this back to `(nil, nil)` because the type information was known statically at the assignment site. The compiler stamped `*User` into the `itab` and moved on.

How `== nil` Works on Interfaces

The `==` operator on an interface checks:

```
(tab == nil) AND (data == nil)
```

Only when **both are zero** is the interface considered nil. State 3 has a non-nil `tab`, so `== nil` is `false` · even though the data pointer inside is nil.

The Classic Bug

```
// BAD
func findUser(found bool) Stringer {
    var u *User              // type: *User, value: nil
    if !found {
        return u             // returns iface{tab: *itab, data:
nil} · NOT nil!
    }
    return &User{Name: "Alice"}
}
result := findUser(false)
if result == nil {           // FALSE · the nil check is BYPASSED
    fmt.Println("not found")
}
result.String()              // PANIC · data is nil, method
dereferences it
```

What the Panic Trace Looks Like

```
n.Notify("hello")                    // interface method call
```

```
  .
runtime loads n.tab.fun[0]           · address of
(*EmailNotifier).Notify · SUCCEEDS
  .
calls (*EmailNotifier).Notify(nil, "hello")   · receiver is nil
  .
inside Notify: e.smtpClient.Send()   · dereferences nil receiver 'e'
  .
PANIC: nil pointer dereference        · error surfaces DEEP INSIDE
the method
Stack trace points at EmailNotifier.Notify, NOT at where you
assigned the typed nil.
This makes production debugging harder · the root cause is far from
the crash site.
```

---

8. The Three Guards Against the Nil Trap

Guard 1 · Fix at the Source (always prefer this)

Never return a typed nil variable through an interface · return bare `nil` directly.

```
// BAD · typed nil leaks in
func findUser(found bool) Stringer {
    var u *User
    if !found {
        return u   // iface{*itab, nil} · bug!
    }
    return &User{Name: "Alice"}
}
// GOOD · return untyped nil
func findUser(found bool) Stringer {
    if !found {
        return nil  // iface{nil, nil} · true nil, == nil check works
    }
    return &User{Name: "Alice"}
}
```

Bare `return nil` in a function returning an interface produces `iface{nil, nil}`.

When to use: Every time you write a function returning an interface type. Make this a habit.

Guard 2 · Type Assertion (when you know the concrete type)

```
func safeCall(s Stringer) {
    u, ok := s.(*User)   // step 1: extract the concrete *User
    if !ok || u == nil {  // step 2: check type match AND nil
pointer
        fmt.Println("skipping · nil or wrong type")
        return
    }
    fmt.Println(u.String()) // safe · u is a non-nil *User
}
```

Under the hood for `s.(*User)` when `s = iface{tab: *itab(*User), data: nil}`:

```
1. Compare s.tab._type.hash == hash(*User) · YES · ok = true
2. Extract s.data · nil · u = nil
· ok is true (type matched) but u is nil (pointer is nil)
  You must check BOTH.
```

When to use: When you know the expected concrete type (e.g., inside a service you control).

Guard 3 · Reflect (last resort, for truly dynamic types)

```
func isTrulyNil(i any) bool {
    if i == nil {
        return true  // fast path: iface{nil, nil}
    }
    v := reflect.ValueOf(i)
    switch v.Kind() {
    case reflect.Ptr, reflect.Interface,
         reflect.Slice, reflect.Map,
         reflect.Chan, reflect.Func:
        return v.IsNil()  // inspects the data word directly
    }
    return false  // int, string, struct etc. can never be nil
}
```

When to use: Generic libraries receiving `any` where you can't know the type. Avoid in hot paths (reflection allocates and is ~10x slower than a type assertion).

Decision Tree

```
You have an interface value and need to know if it's safe to call
methods
·
·· Can you change the code that PRODUCES the interface value?
·   ·· YES · Guard 1: return nil, not a typed nil variable
·
·· NO, you receive it from outside
    ·
    ·· Do you know the concrete type?
    ·   ·· YES · Guard 2: v, ok := i.(*Type); ok && v != nil
    ·
    ·· NO, it's truly dynamic / any
        ·· Guard 3: reflect.ValueOf(i).IsNil()
```

---

9. Type Assertions Under the Hood

Given any interface variable `i` (e.g., `var i Notifier = &EmailNotifier{}`):

Single Type Assertion: `v, ok := i.(ConcreteType)`

```
// i is any interface value · could be Notifier, io.Reader, error,
any, etc.
```

```
// The assertion extracts the concrete type stored inside.
var i Notifier = &EmailNotifier{smtp: "mx.google.com"}
v, ok := i.(*EmailNotifier)   // is the concrete type inside i a
*EmailNotifier?
Under the hood:
1. Read i.tab._type.hash                    // O(1) · hash stored in
itab
2. Compare with hash(*EmailNotifier)        // O(1) · compiler knows
this at build time
3. Match? · ok = true, v = *(*EmailNotifier)(i.data)   // cast the
data pointer
   No match? · ok = false, v = nil (*EmailNotifier zero value)
```

Type Switch: `switch v := i.(type) { ... }`

```
// i is the interface variable you're inspecting.
// The switch tests which concrete type is stored inside.
var i any = 42
switch v := i.(type) {
case int:       // compare i._type.hash with hash(int)     · eface,
not itab (empty interface)
case string:    // compare i._type.hash with hash(string)
case *User:     // compare i._type.hash with hash(*User)
default:        // no match
}
```

The compiler generates a sequence of hash comparisons (or a jump table for many cases). The hash is copied into `itab.hash` specifically to make this fast · no pointer chase needed.

---

10. Performance Implications

Interface Method Calls Cannot Be Inlined

```
func directCall(e *EmailNotifier) { e.Notify("hi") }  // · CAN be
inlined
func ifaceCall(n Notifier)        { n.Notify("hi") }  // · CANNOT be
inlined
```

Why? Inlining requires knowing the target function at compile time. With interfaces, the target lives in `itab.fun[0]` which is only known at runtime.

Production impact: In hot paths processing 100k+ operations/sec, interface dispatch overhead adds up. Consider using concrete types in inner loops and interfaces at boundaries.

Interface Assignment Forces Heap Allocation

```
var n Notifier = &EmailNotifier{smtp: "mx.google.com"}
//                · this value ESCAPES to heap
//                  because iface.data is unsafe.Pointer
```

Every value assigned to an interface must live on the heap (the `data` pointer must remain valid). This creates GC pressure. Verify with:

```
go build -gcflags='-m' ./...
# output: "EmailNotifier{} escapes to heap"
```

Cost Summary

```
.............................................................................
· Operation           · Cost               · Why
   ·
.............................................................................
· Interface assign    · ~30-50ns           · itab lookup + possible heap
   ·
· (first time)        ·                    · alloc + GC bookkeeping
   ·
.............................................................................
· Interface assign    · ~5-15ns            · itab cached, just heap alloc
   ·
· (cached itab)       ·                    ·
   ·
.............................................................................
· Interface method    · ~2-5ns overhead    · Indirect call (load fun ptr
+   ·
· call                · vs direct call     · CALL) · prevents inlining
 ·
.............................................................................
· Type assertion      · ~1-2ns             · Hash comparison + pointer
cast  ·
.............................................................................
· == nil check        · ~0.5ns             · Two pointer comparisons
   ·
.............................................................................
```

---

11. Struct Embedding & Method Promotion

Go doesn't have inheritance. Instead, it uses **embedding** · placing one type inside another to "promote" its methods. This is Go's composition mechanism.

Basic Embedding

```
type Logger struct{}
func (l Logger) Log(msg string) { fmt.Println(msg) }
type Server struct {
    Logger           // embedded · NOT a field name, it's a TYPE
    Addr   string
}
s := Server{Addr: ":8080"}
s.Log("starting")     // · promoted from Logger! As if Server had a
Log method.
```

What the Compiler Actually Does

```
  When you write:     s.Log("starting")
```

```
  Compiler rewrites:  s.Logger.Log("starting")

  There is NO inheritance. No vtable modification. No subclassing.
  The compiler simply forwards the call to the embedded field.

  Memory layout of Server:
  ..............................
  · Server struct              ·
  ·  ........................  ·
  ·  · Logger (embedded)    ·  ·  · 0 bytes (empty struct)
  ·  ........................  ·
  ·  Addr: ":8080"             ·  · string header (16 bytes)
  ..............................

  Logger's methods are "promoted" · accessible through Server
directly.
```

Embedding Satisfies Interfaces

This is the powerful part: if the embedded type satisfies an interface, the **embedding type also satisfies it** · without writing any method:

```
type Writer interface {
    Write([]byte) (int, error)
}
type FileWriter struct {
    File *os.File
}
func (fw FileWriter) Write(data []byte) (int, error) {
    return fw.File.Write(data)
}
type BufferedWriter struct {
    FileWriter        // embeds FileWriter · promotes Write method
    Buffer []byte
}
// BufferedWriter automatically satisfies Writer interface!
var w Writer = BufferedWriter{...}   // · compiles · Write is promoted
```

Embedding Interfaces in Structs

You can embed an **interface** inside a struct. This is used for partial implementation and testing:

```
type ReadCloser interface {
    io.Reader       // embedded interface · promotes Read method
    io.Closer       // embedded interface · promotes Close method
}
// Test double · only implement what you need:
type MockDB struct {
    database.DB     // embed the interface, not the concrete type
}
// Only override the method you're testing:
func (m MockDB) Query(q string) ([]Row, error) {
    return m.fakeData, nil
}
```

```
// All other DB methods panic with "not implemented" · that's fine
for tests
```

Promotion Rules

```
.....................................................................
·  1. Embedded type's exported methods · promoted to outer type      ·
·  2. Embedded type's exported fields · promoted to outer type       ·
·  3. If outer type defines the same method · outer WINS (override)  ·
·  4. If two embedded types have same method · AMBIGUOUS (error)     ·
·  5. Unexported methods/fields are NOT promoted across packages
·
.....................................................................
```

Method Override (Shadowing)

```
type Base struct{}
func (Base) String() string { return "base" }
type Derived struct {
    Base
}
func (Derived) String() string { return "derived" }   // overrides
Base.String
d := Derived{}
fmt.Println(d.String())        // "derived" · Derived's method wins
fmt.Println(d.Base.String())   // "base" · can still access Base's
directly
```

Embedding vs Field · The Difference

```
// EMBEDDING · methods promoted:
type Server struct {
    Logger        // type name only, no field name
}
s.Log("msg")     // · works · Log is promoted
// NAMED FIELD · methods NOT promoted:
type Server struct {
    logger Logger   // lowercase field name
}
s.Log("msg")        // · compile error · Log is NOT promoted
s.logger.Log("msg") // · must access through field name
```

Production Pattern: Composition over Inheritance

```
// Java would use: class HTTPServer extends TCPServer { ... }
// Go uses embedding:
type TCPServer struct {
    Listener net.Listener
}
func (s *TCPServer) Accept() (net.Conn, error) {
    return s.Listener.Accept()
}
```

```
type HTTPServer struct {
    *TCPServer              // embed pointer · share, don't copy
    Router     http.Handler
}
// HTTPServer has Accept() via promotion,
// plus its own ServeHTTP() for HTTP-specific logic.
func (s *HTTPServer) ServeHTTP(w http.ResponseWriter, r
*http.Request) {
    s.Router.ServeHTTP(w, r)
}
```

---

12. Quick Reference Card

```
NON-EMPTY INTERFACE (has methods)
.................................
runtime.iface { tab *itab, data unsafe.Pointer }
  ·· itab { inter *interfacetype, _type *_type, hash uint32, fun
[N]uintptr }
     ·· fun[] = cached method pointers for (interface, concrete type)
pair
     ·· cached globally in runtime.itabTable · built once, reused
forever
EMPTY INTERFACE (interface{} / any)
...................................
runtime.eface { _type *_type, data unsafe.Pointer }
  ·· no method table, just type descriptor + data pointer
  ·· simpler because no methods to dispatch
NIL SEMANTICS
.............
  iface{nil, nil}    == nil  · TRUE   · "true nil" interface
  iface{*itab, nil}  == nil  · FALSE  · "typed nil" TRAP
  iface{*itab, ptr}  == nil  · FALSE  · normal non-nil
COMPILE TIME vs RUNTIME
.......................
  Compile: type checking, code generation, escape analysis, static
itab optimization
  Runtime: itab caching, method dispatch (indirect call), type
assertions, nil checks
TOOLS
.....
  go build -gcflags='-m'      # escape analysis: what goes to heap
  go build -gcflags='-m -m'   # verbose escape analysis with
reasons
  go build -gcflags='-S'      # assembly output: see iface
construction
  go test -race ./...         # race detector: always run
```

One-Line Summary

An interface is a two-word struct `{tab, data}` ·`tab` points to the `itab` (method dispatch table

cached per type pair), `data` points to the value. It's `nil` only when **both** words are zero. The compiler verifies types; the runtime dispatches methods. This is why interface calls can't be inlined.

Deep Dive: The `any` Type, Interface Boxing & Mixed-Type Collections

How Go handles heterogeneous data, what it costs at the runtime level, and why understanding boxing is essential for production performance.

13 Quick Reference Card

---

1. What Is `any` and Where Did It Come From?

The History

Before Go 1.18, the empty interface was written as `interface{}`. It has **zero methods**, which means every type in Go satisfies it · because every type has at least zero methods.

```
// Pre Go 1.18
func Print(v interface{}) { fmt.Println(v) }
// Go 1.18+: `any` is a built-in alias
// In the source code: type any = interface{}
func Print(v any) { fmt.Println(v) }
```

`any` **is not a new type.** It's a type alias defined in the `builtin` package:

```
// From Go source: builtin/builtin.go
type any = interface{}
```

The `=` makes it a **true alias** ·`any` and `interface{}` are identical at the compiler level. No conversion needed, no runtime difference, no performance difference.

Why Does Go Have This?

Go is **statically typed** · every variable has a known type at compile time. But sometimes you genuinely don't know the type:

- JSON parsing of unknown structure
- `fmt.Println` accepting any arguments
- Plugin systems receiving dynamic data
- Database `Scan()` reading columns of unknown types

The empty interface is Go's **escape hatch from the type system**. It says: "I'll accept anything, but I take responsibility for figuring out the type at runtime."

Go Proverb #7: ***"interface{} says nothing."*** · Use it only when you truly must.

---

2. Mixed-Type Collections: `[]any` Under the Hood

Can You Have Mixed-Type Slices?

Yes. `[]any` holds values of different types:

```
mixed := []any{42, "hello", true, 3.14, []int{1, 2, 3}}
```

But what does the runtime actually see? Not a nice heterogeneous list. It sees this:

```
mixed (slice header: 24 bytes)
.......................
· ptr ·......·   · len · cap ·
.......................
           ·
           ·
  Backing array of eface structs (each 16 bytes)
  ....................................................
  · eface[0]                · eface[1]               ·
  · _type · int descriptor  · _type · string descriptor·
  · data  · 42 (see §5)    · data  · "hello" header  ·
  ....................................................
  · eface[2]                · eface[3]               ·
  · _type · bool descriptor · _type · float64 desc    ·
  · data  · true            · data  · 3.14            ·
  ....................................................
  · eface[4]                ·                        ·
  · _type · []int descriptor·                        ·
  · data  · heap ptr to     ·                        ·
  ·         slice header    ·                        ·
  ....................................................
```

Key observations:

- The backing array contains `eface` structs (16 bytes each), NOT the actual values
- Each element is **boxed** · wrapped in a type descriptor + data pointer pair
- The actual data may live elsewhere (heap, static memory, or inlined · see sections below)
- You've lost all compile-time type information · the compiler can't help you

Contrast with Other Languages

| Language | Mixed collection | How it works | |----------|----------------|----------------| | **Python** | `[42, "hello", True]` | Everything is already a PyObject · always boxed | | **Java** | `Object[]` or `List<Object>` | Autoboxing for primitives (`int` · `Integer`), reference types stored directly | | **C#** | `object[]` | Boxing for value types, reference types stored directly | | **Go** | `[]any` | Every element boxed into `eface{_type, data}` · honest about the cost | | **Rust** | `Vec<Box<dyn Any>>` | Explicit boxing with trait objects · even more explicit than Go |

Go's approach: **no hidden cost, no autoboxing magic. You see what you pay for.**

---

3. Boxing: The Conversion from Concrete to Interface

"Boxing" is the process of wrapping a concrete typed value into an interface value. Every time you assign a concrete value to `any` (or any interface), boxing happens.

```
var x int = 42
var a any = x  // BOXING happens here
```

What the Compiler Generates

When the compiler sees `var a any = x`, it emits code to:

1. **Determine the type descriptor** for `int` · this is a compile-time constant pointer to a static `_type` struct in the binary
2. **Copy the value** into a location that `eface.data` can point to
3. **Assemble the eface** · `{_type: &intType, data: pointerToValue}`

The critical question is: **where does the value copy live?** This is where the runtime optimizations come in (sections 4-6).

What Boxing Costs

```
Without boxing:  x is an int on the stack. 8 bytes. Zero GC
involvement.
With boxing:     a is an eface (16 bytes) + potentially a heap copy
of x.
                 The eface.data is a pointer · GC must scan it.
                 Type information is resolved at runtime for type
assertions.
```

The chain of costs:

```
Boxing · heap allocation (maybe) · GC scanning · pointer indirection · no
inlining
```

---

4. The `convT` Family: How the Runtime Boxes Values

When the compiler can't optimize boxing away, it calls one of the `convT` **functions** in the runtime. These are specialized by type category for performance:

```
runtime/iface.go · the convT family
...................................................................
convT(t *_type, v unsafe.Pointer) unsafe.Pointer
  ·· General purpose: allocates heap memory, copies value. Slowest.
```

```
convTnoptr(t *_type, v unsafe.Pointer) unsafe.Pointer
  ·· For types with NO pointers (e.g., struct{x, y int}).
     Uses mallocgc with noscan=true · GC doesn't scan the allocated
block.
     Faster because GC has less work.
convT16(v uint16) unsafe.Pointer
  ·· Specialized for 2-byte values. Checks staticuint64s first.
convT32(v uint32) unsafe.Pointer
  ·· Specialized for 4-byte values. Checks staticuint64s first.
convT64(v uint64) unsafe.Pointer
  ·· Specialized for 8-byte values. Checks staticuint64s first.
convTstring(v string) unsafe.Pointer
  ·· Specialized for strings (16 bytes: pointer + length).
     If empty string · returns pointer to a static zero value.
     Otherwise · allocates and copies the string header.
convTslice(v []byte) unsafe.Pointer
  ·· Specialized for slices (24 bytes: pointer + length + capacity).
     If nil/empty · returns pointer to a static zero value.
     Otherwise · allocates and copies the slice header.
```

The Decision Tree

```
Compiler sees: var a any = someValue
                  .
                  .
        Is the value a pointer type?
        (*T, map, chan, func, unsafe.Pointer)
              .           .
             YES          NO
              .           .
              .           .
    Store pointer      Is it a small integer (0-255)?
    directly in        with size · 8 bytes?
    eface.data              .           .
    (zero cost!)          YES          NO
                            .           .
                            .           .
                     Use staticuint64s   Call convT/convTnoptr
                     (zero allocation!)  (heap allocation)
```

---

5. The `staticuint64s` Optimization: Free Boxing for Small Integers

This is one of Go's cleverest runtime optimizations. In `runtime/iface.go`:

```
// runtime/iface.go
var staticuint64s = [256]uint64{0, 1, 2, 3, ..., 255}
```

This is a **pre-allocated, static array** of 256 uint64 values (0 through 255). It lives in the binary's data segment · never allocated, never garbage collected.

How It Works

When you box a small value:

```
var a any = 42
```

The compiler calls `convT64(42)`. Inside `convT64`:

```
func convT64(v uint64) unsafe.Pointer {
    if v < 256 {
        // Point to the pre-allocated static value · NO ALLOCATION
        return unsafe.Pointer(&staticuint64s[v])
    }
    // Value too large for static cache · allocate on heap
    p := mallocgc(8, uint64Type, false)
    *(*uint64)(p) = v
    return p
}
```

What This Means

```
var a any = 42    // eface.data = &staticuint64s[42]   · NO
allocation
var b any = 255   // eface.data = &staticuint64s[255]  · NO
allocation
var c any = 256   // eface.data = heap-allocated copy   · ALLOCATES
var d any = -1    // int is signed, but bits: 0xFFFFFFFFFFFFFFFF >
255 · ALLOCATES
var e any = 0     // eface.data = &staticuint64s[0]    · NO
allocation
```

Which Types Benefit from `staticuint64s`?

Any type whose binary representation fits in a `uint64` AND has value 0-255:

| Type | Value range for zero-alloc | Example | |------|---------|---------| | `int`, `int64`, `uint`, `uint64` | 0·255 | `var a any = 42` · | `int32`, `uint32` | 0·255 | `var a any = int32(100)` · | `int16`, `uint16` | 0·255 | `var a any = int16(200)` · | `int8`, `uint8`/`byte` | 0·255 (full range for uint8) | `var a any = byte('A')` · | `bool` | true (1), false (0) | `var a any = true` · | `float32` | Only if bits 0-255 (NOT the float value!) | Rarely matches | | `float64` | Only if bits 0-255 (NOT the float value!) | Rarely matches |

Important: For `float64`, the check is on the **binary representation**, not the mathematical value. `float64(1.0)` has bits `0x3FF0000000000000` · way beyond 255. So `var a any = 1.0` **DOES allocate**.

Correction to a Common Misconception

Some sources claim that small values are "stored directly in the data pointer field" (including my earlier explanation · I need to correct that). The truth is more nuanced:

The `data` field is always a pointer. For small values 0-255, it points to the `staticuint64s` array (a static, pre-allocated memory region). The value is NOT stored "inside" the pointer · the pointer points to a shared static location.

For pointer-shaped types (see next section), the actual pointer value IS stored in `data` · but that's because the value itself is already a pointer.

---

6. Direct Interface Types: Zero-Cost Boxing for Pointers

Some types are inherently "pointer-shaped" · their value IS a pointer. For these types, no copying or allocation is needed: the pointer value goes directly into `eface.data`.

Pointer-Shaped Types (Direct Interface)

```
// These types store their value directly in eface.data · ZERO
allocation cost:
var a any = &User{Name: "sam"}   // *User · pointer already, just
copy the pointer
var b any = myMap                 // map is *runtime.hmap under the
hood
var c any = myChan                // chan is *runtime.hchan under
the hood
var d any = myFunc                // func is *runtime.funcval under
the hood
```

Why? Because these types are already pointers in memory. The compiler knows this through a flag called `_type.kind & kindDirectIface`:

```
// runtime/type.go
const kindDirectIface = 1 << 5  // bit flag: type is pointer-shaped
// When this bit is set, the value itself IS a pointer,
// so eface.data = the value itself (no wrapping needed)
```

The Full Picture

```
                              Boxing a value into any
                              ........................
                                        .
                          ...............................
                          .                             .
                  kindDirectIface?                Not pointer-shaped
                  (pointer types)               (value types: int,
string,
                          .                      struct, array, etc.)
                          .                             .
                          .                             .
                  Store pointer value        Need to copy value
somewhere
                  directly in eface.data     eface.data points to copy
                  ....................              .
                  · ZERO allocation  ·    ......................
                  · *T, map, chan,   ·    ·                    .
                  · func, unsafe.Ptr ·    ·              Value > size 0
                  ....................  Value == 0      and not zero?
                                       or zero-sized?          .
                                            .           ...............
                                            .           .             .
                                       Use static      Small
Large
                                       zero value    (0-255, ·8B)   or
non-trivial
```

```
                                        .           .              .
                                        .           .              .
                                   zeroVal[]   staticuint64s
mallocgc()
                                   (no alloc)  (no alloc)      (HEAP
ALLOC)
```

---

7. Which Types Are Cheap vs Expensive to Box?

Here is the definitive cost table for boxing into `any`:

· Free (Zero Allocation)

| Type | Why | Example | |------|-----|---------| | Any pointer `*T` | Pointer-shaped · direct interface | `var a any = &myStruct` | | `map[K]V` | Internally `*hmap` · pointer-shaped | `var a any = myMap` | | `chan T` | Internally `*hchan` · pointer-shaped | `var a any = myChan` | | `func(...)` | Internally `*funcval` · pointer-shaped | `var a any = myFunc` | | `unsafe.Pointer` | Pointer-shaped | `var a any = myPtr` | | Small int 0-255 | `staticuint64s` optimization | `var a any = 42` | | `bool` | `true`=1, `false`=0, both · 255 | `var a any = true` | | `byte` / `uint8` | Full range 0-255 covered | `var a any = byte('A')` | | Zero value of any type | `zeroVal` static buffer | `var a any = 0` |

· Cheap (Small Heap Allocation, No Pointer Scanning)

| Type | Size allocated | Why not free? | |------|---------|---------| | `int` (values > 255) | 8 bytes | Too large for `staticuint64s` | | `float64` | 8 bytes | Binary representation · small integer | | `float32` | 4 bytes | Same reason | | `int32` (values > 255) | 4 bytes | Too large for `staticuint64s` | | `complex64` | 8 bytes | No static cache | | `rune` (> 255) | 4 bytes | UTF-8 codepoints beyond ASCII |

These use `convTnoptr` · `mallocgc` with `noscan=true`, so GC allocates but skips scanning.

· Expensive (Heap Allocation + GC Scanning)

| Type | Size allocated | Why expensive? | |------|---------|---------| | `string` | 16 bytes (header copy) | Contains a pointer · GC must scan | `[]T` (slice) | 24 bytes (header copy) | Contains a pointer · GC must scan | `$struct` with pointer fields | struct size | Contains pointers · full GC scan | `[N]T` array (large) | N × sizeof(T) | Entire array copied to heap |

Why `string` Boxing Is Particularly Interesting

A string in Go is:

```
string header (16 bytes)
.................................
· ptr *byte        · len int      ·
· (pointer to the  · (byte count) ·
·  underlying      ·              ·
·  byte array)     ·              ·
.................................
```

When you box a string into `any`, the runtime copies this 16-byte header to the heap. The actual character data is NOT copied · both the original string and the boxed copy share the same underlying byte array. But the header copy itself allocates 16 bytes, and because the header contains a pointer (`ptr *byte`), the GC must scan it.

This is why `fmt.Sprintf` is slower than `strconv.Itoa` in hot paths:

```
fmt.Sprintf("%d", n)   // n gets boxed into any · allocation · GC
pressure
strconv.Itoa(n)        // no interface, no boxing, can inline
```

---

8. Unboxing: Type Assertions and Type Switches

Getting values back OUT of `any` requires runtime type checking.

Type Assertion

```
var a any = 42
// Safe · comma-ok pattern
v, ok := a.(int)    // v = 42, ok = true
v, ok := a.(string) // v = "", ok = false
// Unsafe · panics on wrong type
v := a.(int)    // v = 42
v := a.(string) // PANIC: interface conversion: interface {} is
int, not string
```

Under the hood: The runtime compares `eface._type` against the target type's `_type` descriptor. This is a pointer comparison (fast) because type descriptors are deduplicated · each type has exactly one `_type` in the binary.

Type Switch

```
func describe(a any) string {
    switch v := a.(type) {
    case int:
        return fmt.Sprintf("int: %d", v)
    case string:
        return fmt.Sprintf("string: %q", v)
    case bool:
        return fmt.Sprintf("bool: %t", v)
    case []int:
        return fmt.Sprintf("[]int with %d elements", len(v))
    case nil:
        return "nil"
    default:
        return fmt.Sprintf("unknown: %T", v)
    }
}
```

Under the hood: The compiler generates a series of `_type` pointer comparisons. For switches with many cases, it may use the `_type.hash` field for a faster hash-based lookup. Inside each case, `v` is already unboxed · no allocation cost.

Performance: Type Switch vs Type Assertion vs Generics

```
Type assertion (single):     ~2ns · one pointer comparison
Type switch (few cases):     ~3-5ns · sequential pointer comparisons
Type switch (many cases):    ~5-10ns · hash-based lookup
Generic function:            ~0ns · type known at compile time, no
runtime check
```

---

9. Equality and Comparison with any

This is a major **interview trap**:

```
var a any = 42
var b any = 42
fmt.Println(a == b)  // true · · ints are comparable
var c any = []int{1, 2}
var d any = []int{1, 2}
fmt.Println(c == d)  // PANIC! · · slices are not comparable
```

The Rule

`any` values can be compared with `==` only if the **underlying concrete type** is comparable. The comparable types in Go:

```
· Comparable (== works):
   bool, int*, uint*, float*, complex*, string,
   pointer, channel, array (if element type is comparable),
   struct (if all fields are comparable), interface
· NOT comparable (== panics at runtime):
   slice, map, func
```

This is a runtime check, not a compile-time check! The compiler can't know what concrete type is inside `any`, so it lets the code compile but panics at runtime.

The `comparable` Constraint (Generics)

Go 1.18 introduced the `comparable` constraint to catch this at compile time:

```
func Contains[T comparable](slice []T, target T) bool {
    for _, v := range slice {
        if v == target {
            return true
        }
    }
    return false
}
Contains([]int{1, 2, 3}, 2)          // · compiles · int is comparable
Contains([][]int{{1}, {2}}, []int{1}) // · compile error · []int is NOT
comparable
```

---

10. Real-World Patterns Using any

Pattern 1: JSON with Unknown Structure

```
// When you don't know the JSON shape at compile time
var data any
json.Unmarshal([]byte(`{"name": "sam", "age": 30, "scores": [95,
87]}`), &data)
```

```
// data is now: map[string]any{
//   "name": "sam",        · string
//   "age":  float64(30),  · JSON numbers are always float64!
//   "scores": []any{float64(95), float64(87)},
// }
// Navigate with type assertions:
m := data.(map[string]any)
name := m["name"].(string)
age := m["age"].(float64)  // NOT int! JSON numbers · float64
```

Interview trap: JSON `Unmarshal` into `any` always produces `float64` for numbers, `map[string]any` for objects, `[]any` for arrays. Never `int`, never `map[string]string`.

Pattern 2: Variadic Functions

```
// fmt.Println signature:
func Println(a ...any) (n int, err error)
// This is why you can pass anything:
fmt.Println(42, "hello", true, []int{1, 2, 3})
// Each argument gets boxed into an eface in the variadic slice
```

Pattern 3: Database Row Scanning

```
// database/sql · Scan takes ...any
rows.Scan(&id, &name, &age)
// Internally, Scan uses type switches to convert database values
// to the concrete types pointed to by your arguments
```

Pattern 4: Plugin / Middleware Data

```
// context.WithValue stores any
ctx = context.WithValue(ctx, "userID", 42)
// Retrieval requires type assertion
userID := ctx.Value("userID").(int)
```

Anti-Patterns · When NOT to Use any

```
// · DON'T: Using any when you know the types
func Sum(values []any) float64 {  // Why not []float64 ?
    total := 0.0
    for _, v := range values {
        total += v.(float64)  // Unnecessary boxing + runtime type
check
    }
    return total
}
// · DON'T: Using any for "generic" code (use generics instead)
func Map(slice []any, f func(any) any) []any { ... }  //
Pre-generics hack
// · DO:
func Map[T, U any](slice []T, f func(T) U) []U { ... }  //
Type-safe, zero boxing
```

```
// · DON'T: Using any for dependency injection
type Service struct {
    repo any  // What methods does it have? Nobody knows!
}
// · DO:
type Service struct {
    repo Repository  // Named interface · clear contract
}
```

---

11. Generics vs `any`: The Modern Choice

Since Go 1.18, most uses of `any` for "generic" code are **obsolete**. Here's the decision framework:

```
Do I know the exact types at compile time?
    ·
    YES · Use concrete types. Always.
    ·
    NO · Is there a finite set of types?
         ·
         YES · Use a named interface with methods, or a type
constraint
         ·
         NO · Is the set of types "anything comparable"?
              ·
              YES · Use generics with `comparable` constraint
              ·
              NO · Is it truly "anything at all"?
                   ·
                   YES · Use `any` (interface{})
                   ·
                   NO · Use a union constraint: `[T int | float64 |
string]`
```

Generics Under the Hood: GC Shape Stenciling

When you write generic code, Go doesn't use `any` internally. It uses **GC Shape Stenciling** · the compiler generates one version per "GC shape":

```
func Max[T int | float64 | string](a, b T) T {
    if a > b { return a }
    return b
}
// Compiler generates:
// Max_int(a, b int) int           · specialized for int
// Max_float64(a, b float64) float64 · specialized for float64
// Max_string(a, b string) string  · specialized for string
// All pointer types share ONE shape (they're all 8-byte pointers)
```

Key insight: Generics give you type safety AND performance (no boxing, inlineable). `any` gives you flexibility but costs boxing, allocations, and runtime type checks.

What Is a "GC Shape"?

A GC shape is determined by how the garbage collector sees a type · specifically, which parts are pointers (need scanning) and which are not:

```
.......................................................................
· Type                  · GC Shape           · Compiler Action
·
.......................................................................
· int, int64, uint      · "8-byte non-ptr"   · Share ONE specialization
·
· float64               · "8-byte non-ptr"   · (same shape as int64!)
·
.......................................................................
· int32, float32        · "4-byte non-ptr"   · Share ONE specialization
·
.......................................................................
· *User, *Order, *any   · "pointer"          · ALL pointers share ONE
·
· pointer type          ·                    · specialization
·
.......................................................................
· string                · "ptr + int"        · Own specialization
·
·                       · (2-word header)    · (unique layout)
·
.......................................................................
· struct{X int; Y *T}   · "int + ptr"        · Own specialization
·
·                       · (unique layout)    · (unique pointer map)
·
.......................................................................
```

Dictionary Passing · The Runtime Cost

For pointer types (which share one shape), the compiler can't inline type-specific operations. Instead, it passes a **dictionary** at runtime:

```
func Print[T any](v T) {
    fmt.Println(v)
}
// For value types (int, string): fully specialized, inlineable
// For pointer types (*User, *Order): one shared version +
dictionary
// The dictionary contains:
//   - Type metadata (for fmt.Println to format correctly)
//   - Method pointers (if T has interface constraints)
//   - Sub-dictionaries (for nested generic calls)

Value type instantiation:     Pointer type instantiation:
Print[int](42)                Print[*User](&u)
  ·                             ·
  ·                             ·
Print_int(42)                 Print_pointer(&u, dict)
  · specialized code             · shared code + dictionary lookup
  · can be inlined               · cannot be inlined (indirect call)
```

```
  · zero overhead                · small overhead (~2-5ns)
```

Generics vs any · Performance Comparison

```
// Generic version · type-safe, no boxing:
func SumGeneric[T int | float64](vals []T) T {
    var total T
    for _, v := range vals { total += v }
    return total
}
// any version · type assertion, boxing:
func SumAny(vals []any) any {
    var total float64
    for _, v := range vals {
        switch n := v.(type) {      // type switch · runtime cost
        case int: total += float64(n)
        case float64: total += n
        }
    }
    return total
}

Benchmark comparison:
  SumGeneric[int] (1000 elements):   ~800ns,   0 allocs
  SumAny         (1000 elements):   ~5000ns, 1000 allocs (boxing
each int!)

  Generics: 6x faster, zero GC pressure
```

Comparison with Java/C#/Rust

```
.......................................................................
· Language · Strategy         · Tradeoffs                            ·
.......................................................................
· Java     · Type erasure     · Generic info LOST at runtime         ·
·          ·                  · Always boxes primitives · GC pressure ·
·          ·                  · Binary size: small (one copy)        ·
.......................................................................
· C#       · Reification      · Full specialization for value types  ·
·          ·                  · Type info available at runtime       ·
·          ·                  · Binary size: larger (many copies)    ·
.......................................................................
· Rust     · Monomorphization · Full specialization for EVERY type   ·
·          ·                  · Zero runtime cost, fully inlineable  ·
·          ·                  · Binary size: can be very large       ·
.......................................................................
· Go       · GC Shape         · Hybrid: specialize per GC shape      ·
·          · Stenciling       · Value types: specialized (fast)      ·
·          ·                  · Pointer types: shared + dictionary   ·

```

12. Performance Impact: Benchmarks and Escape Analysis

Boxing Cost Demonstration

```
// Concrete · zero allocation
func sumConcrete(nums []int) int {
    total := 0
    for _, n := range nums {
        total += n
    }
    return total
}
// Boxed · allocation per element
func sumBoxed(nums []any) int {
    total := 0
    for _, n := range nums {
        total += n.(int)  // type assertion + unboxing
    }
    return total
}
```

Expected benchmark results:

```
BenchmarkSumConcrete-8    ~0 allocs/op    ~50ns for 1000 elements
BenchmarkSumBoxed-8       varies          ~500ns+ for 1000 elements
```

The concrete version is faster because:

1. **No type assertions** · CPU doesn't check types
2. **No pointer indirection** · values are contiguous in memory (cache-friendly)
3. **Inlineable** · compiler can optimize the loop body
4. **No GC scanning** · `[]int` has no pointers

Escape Analysis Proof

```
$ go build -gcflags='-m' ./...
# var a any = x  ·  "x escapes to heap"
# var a int = x  ·  (no escape message · stays on stack)
```

---

13. Quick Reference Card

```
.......................................................................
·                        any / interface{} CHEAT SHEET
    .
.......................................................................
·
    .
·  WHAT:  any = interface{} = empty interface = zero methods
    .
·         Runtime struct: eface{_type *_type, data unsafe.Pointer}
   .
·         Size: 16 bytes (two pointers)
```

```
BOXING COST:

  Pointer types (*T, map, chan, func)  · FREE (direct interface)

  Small ints 0-255                     · FREE (staticuint64s)

  bool                                 · FREE (0 or 1)

  Larger scalars (int > 255, float64)  · 8B heap alloc (no GC scan)

  string                               · 16B heap alloc (GC scans)

  slice                                · 24B heap alloc (GC scans)

  large struct                         · full struct heap alloc

TYPE RECOVERY:

  v, ok := a.(int)        // safe assertion

  v := a.(int)            // panics if wrong

  switch v := a.(type) {} // type switch (preferred)

EQUALITY TRAP:

  any(42) == any(42)            · true  (ints comparable)

  any([]int{}) == any([]int{})  · PANIC  (slices not comparable)

WHEN TO USE:

  · JSON parsing unknown structure

  · fmt.Println variadic args

  · database/sql Scan

  · reflect-based frameworks

  · "Generic" code · use generics instead
  · Dependency injection · use named interfaces
  · When you know the types · use concrete types
```

```
·  GENERICS vs any:
   ·
·    Generics: type-safe, inlineable, zero boxing, compile-time
errors   ·
·    any: flexible, runtime type checks, boxing cost, runtime panics
   ·
·
    ·
.......................................................................
```

Key Takeaways

1. `any` **is** `interface{}` · **a type alias, nothing more.** Same runtime behavior.
2. **Boxing is the hidden cost.** Every value assigned to `any` gets wrapped in an `eface{_type, data}`. The cost depends on the value type.
3. **Three zero-cost boxing paths:** direct interface (pointers), staticuint64s (small ints), and zero values.
4. **The GC cost is the real killer.** Boxed values with pointers (strings, slices, structs with pointer fields) force GC scanning · this is where performance degrades at scale.
5. **Post-generics, the legitimate uses of** `any` **are narrow.** If you're reaching for `[]any`, ask: "Could I use `[T any]` instead?" If yes, always prefer generics.
6. `any` **is Go's honest version of Java's** `Object`**.** Same concept, but Go makes you see the boxing cost explicitly through escape analysis and benchmarks.

> *"interface{} says nothing."* · Go Proverbs
> But `any` says one thing clearly: **"I've traded compile-time safety for runtime flexibility."** Make sure the trade is worth it.

---

12 · Context Interface Deep Dive

Why `context.Context` Is the Best Example of Interfaces in Go

This document explains what `context.Context` is, why it's an interface (not a struct), and how its design embodies Go's interface philosophy.

---

1. The Interface · Just 4 Methods

```go
type Context interface {
    Deadline() (deadline time.Time, ok bool)
    Done() <-chan struct{}
    Err() error
    Value(key any) any
}
```

That's it. Four methods. No fields, no inheritance, no framework. Any type that has these four methods **is** a `Context` · the Go compiler guarantees it.

Method	Purpose
`Deadline()`	Returns the time when this context will be cancelled (if any)
`Done()`	Returns a channel that closes when the context is cancelled
`Err()`	Returns **why** the context was cancelled (`Canceled` or `DeadlineExceeded`)
`Value(key)`	Retrieves a request-scoped value by key

2. The Concrete Implementations (What the stdlib Actually Creates)

The `context` package has **four unexported structs**. Each one does exactly **one thing**:

`emptyCtx` · The Root (Does Nothing)

```
type emptyCtx struct{}
func (emptyCtx) Deadline() (time.Time, bool) { return time.Time{},
false }
func (emptyCtx) Done() <-chan struct{}        { return nil }
func (emptyCtx) Err() error                   { return nil }
func (emptyCtx) Value(key any) any            { return nil }
```

This is what `context.Background()` and `context.TODO()` return. It never cancels, has no deadline, stores no values. It's the **zero-value anchor** of the chain.

`cancelCtx` · Adds Cancellation

```
type cancelCtx struct {
    Context              // · embeds the INTERFACE (parent)
    done    chan struct{} // closed on cancel
    err     error         // set on cancel
}
```

It **embeds the parent as an interface**, not as a concrete type. It only adds a `done` channel and an `err`. Everything else (`Deadline()`, `Value()`) is delegated to the parent via the embedded interface.

`timerCtx` · Adds Deadline/Timeout

```
type timerCtx struct {
    *cancelCtx           // embeds cancelCtx (inherits
cancellation)
    timer    *time.Timer // fires at deadline
    deadline time.Time
}
```

Wraps a `cancelCtx`, adds a timer. Only overrides `Deadline()` · cancellation behavior comes from the embedded `cancelCtx`, and `Value()` still delegates up the chain.

`valueCtx` · Adds One Key-Value Pair

```
type valueCtx struct {
    Context        // · embeds the INTERFACE (parent)
    key, val any   // ONE key-value pair, not a map
}
func (c *valueCtx) Value(key any) any {
```

```
    if c.key == key {
        return c.val  // found it
    }
    return c.Context.Value(key)  // not mine, ask parent
}
```

This is critical: each `WithValue()` call creates a **new node** holding exactly one key-value pair. It doesn't add to a map · it creates a linked list of single-value wrappers.

---

3. How the Chain Works · Step by Step

```
ctx := context.Background()                        // emptyCtx{}
ctx  = context.WithValue(ctx, "userID", 42)         //
valueCtx{parent: emptyCtx, key: "userID", val: 42}
ctx  = context.WithCancel(ctx)                      //
cancelCtx{parent: valueCtx{...}}
ctx  = context.WithValue(ctx, "traceID", "abc-123") //
valueCtx{parent: cancelCtx{...}, key: "traceID", val: "abc-123"}
```

The chain in memory looks like:

```
valueCtx("traceID"="abc-123")
  ·
  ···· cancelCtx (has done channel)
         ·
         ···· valueCtx("userID"=42)
                ·
                ···· emptyCtx (the root)
```

What Happens When You Call `ctx.Value("userID")`?

```
Step 1: valueCtx("traceID") · key is "traceID", not "userID" · ask
parent
Step 2: cancelCtx           · doesn't override Value() · ask parent
Step 3: valueCtx("userID")  · key matches! · return 42
```

What Happens When You Call `cancel()`?

The `cancelCtx` closes its `done` channel. Any goroutine doing this immediately unblocks:

```
select {
case <-ctx.Done():
    return ctx.Err()  // context.Canceled
case result := <-workCh:
    return result
}
```

Cancellation propagates **downward** · children of the cancelled context also get cancelled · it does **not** propagate upward · the parent remains alive.

---

4. What If Context Were a Struct?

This is where the interface design becomes obvious.

The Struct Version (Hypothetical)

```
type Context struct {
    deadline  time.Time
    hasDL     bool
    done      chan struct{}
    err       error
    values    map[any]any
    parent    *Context
    cancelFn  func()
    timer     *time.Timer
}
```

Problems with the Struct Approach

Problem 1: Every Context Pays for Every Feature

```
ctx := context.Background()
// With struct: allocates deadline, timer, values map, done
channel...
//              even though Background() needs NONE of them
// With interface: emptyCtx is literally struct{} · zero bytes of
useful data
```

In a high-throughput server handling 50k requests/sec, each request creates a context chain. The struct approach wastes memory on unused fields across millions of allocations.

Problem 2: You Can't Extend It

What if a library needs a context with custom behavior · say, a context that logs every cancellation? With the interface:

```
type loggingCtx struct {
    context.Context              // embed the interface
    logger *slog.Logger
}
func (c *loggingCtx) Done() <-chan struct{} {
    ch := c.Context.Done()
    c.logger.Info("someone checked Done()")
    return ch
}
```

Done. It satisfies `context.Context`. It wraps any existing context. It works with every function in the stdlib that accepts `context.Context`.

With a struct? **Impossible.** You can't override methods on a struct you don't own. You'd need the `context` package to anticipate every possible extension · which violates Go's design philosophy entirely.

Problem 3: Single Responsibility Collapses

The interface design gives each wrapper **one job**:

Type	Responsibility	Fields Added

`emptyCtx`	Be the root	none	
`cancelCtx`	Cancellation	`done`, `err`	
`timerCtx`	Deadline-based cancel	`timer`, `deadline`	
`valueCtx`	One key-value pair	`key`, `val`	

With a struct, all responsibilities collapse into one type. Adding a new feature (like `context.WithoutCancel` added in Go 1.21) means modifying the struct, adding fields, adding branching logic. With the interface, it's just a new wrapper type.

Problem 4: Testing Becomes Rigid

With the interface, you can create test-specific contexts:

```
type alwaysCancelledCtx struct{}
func (alwaysCancelledCtx) Deadline() (time.Time, bool)  { return
time.Time{}, false }
func (alwaysCancelledCtx) Done() <-chan struct{}         { ch :=
make(chan struct{}); close(ch); return ch }
func (alwaysCancelledCtx) Err() error                   { return
context.Canceled }
func (alwaysCancelledCtx) Value(key any) any             { return
nil }
```

Pass this to any function that takes `context.Context` · it immediately triggers the cancellation path. With a struct, you'd need to create a real context chain and actually cancel it, or the struct would need test-only fields.

---

5. The Design Pattern: Decorator / Wrapper

What `context.Context` demonstrates is the **decorator pattern** in Go:

```
.......................................................
·  Each wrapper:                                      ·
·    1. Holds the parent as an INTERFACE               ·
·    2. Overrides only the methods it cares about      ·
·    3. Delegates everything else to the parent        ·
·    4. Is itself an implementation of the interface    ·
·       · so it can be wrapped by the NEXT layer       ·
.......................................................
```

This pattern appears everywhere in Go's stdlib:

```
// io.Reader chain · same decorator pattern
file, _ := os.Open("data.gz")         // *os.File       · io.Reader
buf := bufio.NewReader(file)           // bufio.Reader   · wraps
io.Reader
gz, _ := gzip.NewReader(buf)           // gzip.Reader    · wraps
io.Reader
limited := io.LimitReader(gz, 1024)    // LimitedReader  · wraps
io.Reader
// http.Handler chain · same pattern
handler := myHandler{}                                   //
implements http.Handler
handler = loggingMiddleware(handler)                      // wraps
http.Handler
handler = authMiddleware(handler)                         // wraps
http.Handler
```

```
handler = rateLimitMiddleware(handler)                    // wraps
http.Handler
```

In every case, the interface is what makes the stacking possible. Each wrapper doesn't know or care what's inside it · it only knows the interface contract.

---

6. Summary · Why Context Must Be an Interface

Concern	Struct	Interface ·
Memory efficiency	All fields always allocated	Each wrapper carries only what it needs
Extensibility	Modify the one struct (breaking change)	Add a new wrapper type (non-breaking)
Single responsibility	One type does everything	Each type does one thing
Third-party extension	Impossible without forking	Implement 4 methods, done
Testability	Must use real context chain	Create a fake in 10 lines
Composition	Flat, rigid	Stackable, infinitely composable

The Go Philosophy This Embodies

1. **"The bigger the interface, the weaker the abstraction"** · 4 methods is all you need
2. **"Accept interfaces, return concrete types"** · `WithCancel` accepts `Context` (interface), returns `Context` (interface wrapping a concrete `cancelCtx`)
3. **Consumer defines the contract** · any package can create a custom `Context` implementation
4. **Composition over inheritance** · behavior is built by stacking wrappers, not by subclassing

---

7. Production Gotchas

Value Lookup is O(n)

Each `Value()` call walks the linked list. Deep chains = slow lookups:

```
// 100 WithValue calls = 100-node linked list
// Value() on the outermost walks up to 100 nodes
```

Rule: Keep context values shallow. Use them for request-scoped metadata (trace IDs, request IDs), **not** for dependency injection.

Cancellation is One-Way (Parent · Children)

```
parent ··cancel··· child1 ·
                   child2 ·
child1 ··cancel··· parent ·  (parent is unaffected)
```

Don't Store Context in Structs

```
// · Anti-pattern
type Service struct {
    ctx context.Context  // which request does this belong to?
}
// · Pass as first parameter
```

```
func (s *Service) Process(ctx context.Context, data []byte) error {
... }
```

Context is **request-scoped** and short-lived. Struct fields are long-lived. Mixing them creates confusing lifecycles and potential goroutine leaks.

Always Check `ctx.Err()` Before Expensive Operations

```
func process(ctx context.Context, items []Item) error {
    for _, item := range items {
        if err := ctx.Err(); err != nil {
            return err  // bail early if cancelled
        }
        // ... expensive work ...
    }
    return nil
}
```

---

8. Mental Model · The Final Picture

Think of `context.Context` as a **Russian nesting doll** (matryoshka):

```
...............................................
·  valueCtx("traceID" = "abc")                 ·
·  ........................................   ·
·  ·  cancelCtx (done channel)              ·   ·
·  ·  ...................................  ·   ·
·  ·  ·  valueCtx("userID" = 42)         ·  ·   ·
·  ·  ·  ............................   ·  ·   ·
·  ·  ·  ·  emptyCtx (Background)     ·   ·  ·   ·
·  ·  ·  ............................   ·  ·   ·
·  ·  ...................................  ·   ·
·  ........................................   ·
...............................................
```

Each doll:

- Adds exactly one capability
- Delegates everything else inward
- Only knows the **interface** of the doll inside it
- **Is itself** a valid `Context` that can be put inside another doll

This is only possible because the "shape" each doll must match is an **interface**, not a specific struct. That's the entire lesson.

Deep Dive: Go Error Handling · Patterns, Internals & Enterprise Strategy

How Go represents errors at runtime, how wrapping builds linked chains, how errors.Is/As walk those chains, and how to architect error handling across service layers in production.

---

1. The `error` Interface · Under the Hood

The `error` type is not a keyword · it's a **plain interface** in the `builtin` package:

```
type error interface {
    Error() string
}
```

One method. Any type with `Error() string` satisfies it.

Runtime Representation

Since `error` has one method, it is a **non-empty interface**. At runtime, every `error` value is a `runtime.iface` · the same 16-byte two-word struct from the interface deep dive:

```
error value at runtime = runtime.iface (16 bytes)
.................................................
·  tab  *itab           ·  data unsafe.Pointer ·
·  {                    ·  (pointer to the     ·
·   inter: error        ·   concrete value:    ·
·   _type: *errorString·   *errorString,       ·
·   fun[0]: Error()     ·   *PathError, etc.)  ·
·  }                    ·                      ·
.................................................
```

Key connection: The `itab` is cached globally per (error, concrete type) pair. Method dispatch through `error` is an indirect call via `itab.fun[0]` · cannot be inlined.

The Zero Value: nil = Success

```
var err error   // iface{nil, nil} · both words zero
err == nil · TRUE · this IS the success case in Go
```

Why Not Exceptions?

Rob Pike and the Go team chose explicit error returns because:

1. **Exceptions hide control flow** · Go `(result, error)` makes the error path visible
2. **Exception handling is lazy** · try/catch swallows errors; Go forces per-call handling
3. **Stack unwinding is expensive** · Go errors are just values, no runtime cost until wrapped
4. **"Errors are values"** · you can store them, pass them, aggregate them in slices

Source: Go FAQ ("Why does Go not have exceptions?"), Rob Pike's "Errors are Values" (2015).

---

2. Creating Errors · The Four Ways

(a) `errors.New("msg")` · The Simplest Error

Returns `*errorString` (unexported struct):

```
// errors/errors.go
func New(text string) error { return &errorString{text} }
type errorString struct{ s string }
func (e *errorString) Error() string { return e.s }

err (iface):
.....................................
· tab: itab{       · data ............... errorString{s: "connection refused"}
·   error,         ·                  ·    (heap allocated · 1 alloc)
·   *errorString}  ·                  ·
.....................................
```

(b) `fmt.Errorf("%w", err)` · Wrapping with Context

With `%w`, returns `*fmt.wrapError`:

```
// fmt/errors.go (simplified)
type wrapError struct {
    msg string
    err error   // the wrapped error
}
func (e *wrapError) Error() string { return e.msg }
func (e *wrapError) Unwrap() error { return e.err }
```

(c) Custom Error Types · Struct with `Error()`

```
type ValidationError struct{ Field, Message string }
func (e *ValidationError) Error() string {
    return fmt.Sprintf("validation: %s · %s", e.Field, e.Message)
}
```

(d) Sentinel Errors · Package-Level Variables

```
var ErrNotFound = errors.New("not found")
var ErrTimeout  = errors.New("operation timed out")
```

When to Use Each

```
.......................................................................
· Method              · When to Use
 .
.......................................................................
· errors.New()        · Simple, one-off errors. Not part of API
contract.·
.......................................................................
· fmt.Errorf("%w")    · Adding context while preserving the cause.
 .
.......................................................................
· Custom error type   · Domain errors carrying structured data.
 .
.......................................................................
· Sentinel error      · Well-known conditions callers must check for.
 .
.......................................................................
```

---

3. Sentinel Errors

A sentinel error is a **package-level variable** representing a specific, known condition.

```
var ErrNotFound   = errors.New("not found")       // Convention:
prefix with "Err"
var ErrPermission = errors.New("permission denied")
```

Standard Library Examples

```
io.EOF                    // end of stream · a signal, not really an
"error"
sql.ErrNoRows             // query returned zero rows
os.ErrNotExist            // file/dir does not exist
context.Canceled          // context was canceled
context.DeadlineExceeded  // context deadline passed
```

How to Check: `errors.Is()`, Not ==

```
if errors.Is(err, io.EOF) { }     // GOOD · works through wrapping
chains
if err == io.EOF { }               // BAD · breaks if err is wrapped
if err.Error() == "EOF" { }        // TERRIBLE · fragile, breaks on
typo
```

API Contract Implications

Sentinel errors are part of your **public API.** Once exported, callers depend on them. You can't rename, change meaning, or remove without breaking downstream code.

```
 Package "repo"                      Caller code
 ................                    ........................
 var ErrNotFound = errors.New(...)  if errors.Is(err,
repo.ErrNotFound) {
 This is an API contract ...........    // handle 404
                                     }
```

---

4. Custom Error Types

When an error needs to carry **structured data** beyond a message string:

```
type ValidationError struct{ Field, Message string }
func (e *ValidationError) Error() string {
    return fmt.Sprintf("validation failed: field %q · %s", e.Field,
e.Message)
}
type NotFoundError struct{ Resource, ID string }
func (e *NotFoundError) Error() string {
    return fmt.Sprintf("%s %q not found", e.Resource, e.ID)
}
```

Interface Satisfaction & Extraction

```
Compiler sees: var err error = &ValidationError{...}
  Does *ValidationError have Error() string?  ·
  ·· Satisfies error · iface{itab, data} is constructed

var ve *ValidationError
if errors.As(err, &ve) {
    fmt.Printf("field: %s, message: %s\n", ve.Field, ve.Message)
// structured access
}
```

Rule: Use sentinels when callers only need the category. Use custom types when callers need to extract data (field name, status code, resource ID).

---

5. Error Wrapping · The %w Verb

The Core Mechanism

```
original := errors.New("connection refused")
wrapped  := fmt.Errorf("database: query users: %w", original)
// wrapped.Unwrap() returns original · chain is preserved
```

The Wrapping Chain as a Linked List

```
err1 := errors.New("connection refused")
```

```
err2 := fmt.Errorf("postgres: query failed: %w", err1)
err3 := fmt.Errorf("user service: get user 42: %w", err2)
err4 := fmt.Errorf("GET /api/users/42: %w", err3)

err4 (surface)
.........................................
· wrapError{                              ·
·   msg: "GET /api/users/42: ..."         ·
·   err ................................  ·
· }                                     ·  ·
.........................................
                                        ·
err3  ......................................
      · wrapError{                        ·
      ·   msg: "user service: get user 42:·"·
      ·   err ........................... ·
      · }                               ·  ·
      ......................................
                                        ·
err2  ......................................
      · wrapError{                        ·
      ·   msg: "postgres: query failed: ·"  ·
      ·   err ........................... ·
      · }                               ·  ·
      ......................................
                                        ·
err1  ......................................
      · errorString{s: "connection refused"}·
      · (no Unwrap · chain ends here)      ·
      ......................................
```

%w vs %v · The Critical Difference

```
fmt.Errorf("query: %w", err)   // WRAPS: chain preserved,
errors.Is/As work
fmt.Errorf("query: %v", err)   // FORMATS: chain BROKEN, original
err lost
```

Use `%w` when callers need to inspect the cause. Use `%v` to intentionally **hide** internal error types at an API boundary.

---

6. `errors.Is()` · Sentinel Matching Through the Chain

Walks the entire `Unwrap()` chain looking for a target match.

The Algorithm

```
// errors/wrap.go (simplified)
func Is(err, target error) bool {
    for {
        if err == target { return true }                    //
pointer equality
        if x, ok := err.(interface{ Is(error) bool }); ok {
```

```
            if x.Is(target) { return true }                  //
custom Is()
        }
        switch x := err.(type) {
        case interface{ Unwrap() error }:
            err = x.Unwrap()                                 //
walk deeper
        case interface{ Unwrap() []error }:
            for _, e := range x.Unwrap() {
                if Is(e, target) { return true }             //
recurse branches
            }
            return false
        default:
            return false                                     //
chain exhausted
        }
    }
}
```

Step-by-Step Trace

```
var ErrConnRefused = errors.New("connection refused")
err := fmt.Errorf("service: %w", fmt.Errorf("repo: %w",
ErrConnRefused))
errors.Is(err, ErrConnRefused)   // · true

Step 1: err = wrapError{"service: repo: connection refused"}
        err == ErrConnRefused? NO · Unwrap()
Step 2: err = wrapError{"repo: connection refused"}
        err == ErrConnRefused? NO · Unwrap()
Step 3: err = errorString{"connection refused"}  · IS ErrConnRefused
        err == ErrConnRefused? YES ·
```

Custom `Is()` Method

```
type HTTPError struct{ Code int; Message string }
func (e *HTTPError) Error() string { return fmt.Sprintf("%d: %s",
e.Code, e.Message) }
func (e *HTTPError) Is(target error) bool {
    t, ok := target.(*HTTPError)
    return ok && e.Code == t.Code   // match by status code only
}
err := &HTTPError{Code: 404, Message: "user not found"}
errors.Is(err, &HTTPError{Code: 404, Message: ""})  // true · codes
match
```

---

7. `errors.As()` · Type Extraction Through the Chain

Walks the chain looking for an error assignable to the target type. Uses reflection.

Step-by-Step Trace

```
inner := &os.PathError{Op: "open", Path: "/etc/secret", Err:
os.ErrPermission}
wrapped := fmt.Errorf("config: load: %w", inner)
var pe *os.PathError
errors.As(wrapped, &pe)   // · true

Step 1: err = wrapError{"config: load: open /etc/secret: permission
denied"}
        Is *wrapError assignable to *os.PathError? NO · Unwrap()
Step 2: err = &os.PathError{Op:"open", Path:"/etc/secret"}
        Is *os.PathError assignable to *os.PathError? YES ·
        pe.Op = "open", pe.Path = "/etc/secret", pe.Err =
os.ErrPermission
```

`errors.As()` Runtime Internals · What Actually Happens

`errors.As` uses `reflectlite` (a slimmed-down reflection package) to inspect types at runtime. Here's the simplified source from `src/errors/wrap.go`:

```
func As(err error, target any) bool {
    val := reflectlite.ValueOf(target)       // reflection on
target pointer
    targetType := val.Type().Elem()          // the type target
points to (*DNSError · DNSError)
    for {
        // KEY: type assignability check via reflection
        if reflectlite.TypeOf(err).AssignableTo(targetType) {
            val.Elem().Set(reflectlite.ValueOf(err))   // set
*target = err
            return true
        }
        // Check if err implements custom As(target) method
        if x, ok := err.(interface{ As(any) bool }); ok {
            if x.As(target) { return true }
        }
        // Unwrap and continue down the chain
        err = Unwrap(err)
        if err == nil { return false }
    }
}
```

What's happening at the iface/itab level:

```
errors.As(err, &dnsErr)
  ·
  ·· reflectlite reads err's iface · itab · _type (concrete type
descriptor)
  ·· compares _type against *DNSError's type descriptor
  ·   ·· match? · set target via reflection, return true
  ·   ·· no match? · type-assert err.(interface{ Unwrap() error })
  ·                    ·· itab lookup: does concrete type have
Unwrap()?
```

```
·                          ·· yes · call Unwrap(), loop with inner error
·                          ·· no · return false
·· walks the entire wrap chain until match or nil
```

Performance note: `errors.As` uses reflection, making it ~10× slower than a directtype assertion. In hot paths where you know the error isn't wrapped, prefer direct:

```
// Fast · direct itab lookup, pointer comparison, no reflection
(~5ns):
if dnsErr, ok := err.(*DNSError); ok { ... }
// Slower but walks wrapped chains · reflection at each level
(~50-100ns per level):
var dnsErr *DNSError
if errors.As(err, &dnsErr) { ... }
```

Use `errors.As` when errors might be wrapped with `fmt.Errorf("%w")`. Use direct type assertions when you know the error is unwrapped.

`errors.Is()` vs `errors.As()`

```
errors.Is(err, target)   · "Does the chain contain this VALUE?"
                            Use with sentinels: errors.Is(err,
io.EOF)
errors.As(err, &target)  · "Does the chain contain this TYPE?"
                            Use with custom types: errors.As(err,
&ve)
```

7b. Type Assertions · The Runtime Machinery Behind Error Inspection

Type assertions are a **Go 1.0 language feature** · they've existed since Go's first release (2012). They work **only on interface values** because that's the only case where the concrete type is unknown at compile time.

Why Only Interfaces?

With a concrete type (`var x int`), the compiler already knows the type · there's nothing to "assert." With an interface, the concrete type is hidden behind the `iface`/`eface` wrapper, so runtime machinery is needed to recover it.

How It Works at Runtime

```
var err error = &DNSError{Host: "example.com"}
dnsErr, ok := err.(*DNSError)   // type assertion

err is an iface { tab *itab, data unsafe.Pointer }
                    ·
                    ·· itab { inter *interfacetype,  // error
interface
                              _type *_type,           // concrete:
*DNSError
                              fun   [1]uintptr }      // method:
Error()
Type assertion does:
1. Read itab._type from the iface
```

```
2. Compare itab._type against the _type descriptor for *DNSError
3. This is a POINTER COMPARISON · each type has exactly one _type in
the binary
4. Match? · return ((*DNSError)(iface.data), true)
5. No match? · return (nil, false)
```

Cost: Essentially a pointer comparison + pointer cast. Near zero (~1-2ns). Much cheaper than Java's `instanceof` which may walk the class hierarchy.

The Two Forms

```
// Safe form · program continues:
val, ok := iface.(ConcreteType)   // ok=false if wrong type
// Panic form · crashes if wrong:
val := iface.(ConcreteType)       // panics if assertion fails ·
avoid in production
```

Connection to errors.As

`errors.As` is essentially a loop of type-assertion-like checks using reflection, walking the `Unwrap()` chain. A direct type assertion is the fast path; `errors.As` is the general-purpose path for wrapped error chains.

```
Direct type assertion:  iface._type == target._type         · ~1-2ns
errors.As:              reflectlite.TypeOf(err) per level    ·
~50-100ns × chain depth
```

7c. Why Errors Are Interfaces, Not Strings

If `error` were just a `string`, you could only read the message. The interface enables **programmatic inspection**:

```
// With strings · fragile string matching:
if err == "connection refused" { retry() }   // breaks if wording
changes
// With error interface · carry structured data + identity:
type DNSError struct {
    Host    string
    Timeout bool
}
func (e *DNSError) Error() string { return "dns lookup failed: " +
e.Host }
var dnsErr *DNSError
if errors.As(err, &dnsErr) {
    if dnsErr.Timeout { retry() }        // structured inspection
    else { alertOncall() }               // branch on data, not
strings
}
```

What the interface buys over strings:

Strings	`error` Interface
Compare by text (fragile)	Compare by identity with `errors.Is()`
No metadata	Carry fields: status codes, retry info, context
Can't type-switch	`errors.As()` unwraps to concrete types
Can't wrap	

`fmt.Errorf("ctx: %w", err)` builds chains | | Dead data | Programmable: store in maps, send on channels |

Design insight: `Error() string` is for **humans** (logging, display). The **type itself** is for **code** (branching, inspection, wrapping). That separation is the entire design.

7d. Java-to-Go Error Model Mental Bridge

For engineers coming from Java/C#, the error model is the biggest mental shift.

Mapping Table

Java/C#	Go	Key Difference
`throw new Exception("msg")`	`return fmt.Errorf("msg")`	Java unwinds stack; Go just returns
`try { ... } catch (E e) { ... }`	`if err != nil { ... }`	Go has no implicit control flow
`throws IOException` in signature	`error` as return type	Both visible; Go is simpler
Unchecked `RuntimeException`	`panic()` (rare, not for errors)	Go reserves panic for truly fatal bugs
`finally { ... }`	`defer func() { ... }()`	Go's defer runs on ALL exit paths
`instanceof` (class hierarchy)	Type assertion (pointer compare)	Go is faster: no hierarchy walk
Stack trace captured at creation	No stack trace by default	Go errors are cheap; add context via %w

The Fundamental Shift

```
Java:   CREATING an exception and THROWING it are separate but
almost always paired.
        The "throw" triggers stack unwinding · an expensive,
invisible control flow jump.
Go:     There is NO "throw" step. You create the error and RETURN
it.
        The caller checks it explicitly. No invisible jumps, no
unwinding.
        The only thing that gives errors power is YOUR CODE
checking them.
```

What Happens When You Ignore an Error

```
// Java · compiler forces you to handle checked exceptions:
file.read();   // won't compile without try/catch or throws
declaration
// Go · compiles and runs fine, error silently dropped:
divide(10, 0)              // both return values discarded · no
warning
fmt.Println("life goes on") // runs as if nothing happened
// The danger in production:
db.Exec("DELETE FROM users WHERE id = $1", userID)   // what if
this failed?
fmt.Println("user deleted!")                           // lies.
```

Go's compiler **trusts you**. The language enforces that declared variables are used, but if you never assign the returns, it's legal. Tooling catches this:

- `go vet` · warns about some ignored errors

- `errcheck` linter · catches ALL unhandled error returns
- `golangci-lint` · bundles errcheck and more

In enterprise Go, running linters in CI is non-negotiable.

---

8. `errors.Join()` (Go 1.20+)

Combines multiple errors into one. Returns `Unwrap() []error` (multi-error tree).

```
// errors/join.go
type joinError struct{ errs []error }
func (e *joinError) Unwrap() []error { return e.errs }  // · SLICE,
not single

joinError
.........................................
· errs []error                           ·
·  ·· [0] "name required"               ·
·  ·· [1] "email invalid"               ·  errors.Is/As check ALL
branches
·  ·· [2] "age positive"                ·
.........................................
```

Use Cases

```
// Multi-field validation
func validate(u User) error {
    var errs []error
    if u.Name == "" { errs = append(errs, fmt.Errorf("name: %w",
ErrRequired)) }
    if !validEmail(u.Email) { errs = append(errs,
fmt.Errorf("email: %w", ErrInvalid)) }
    return errors.Join(errs...)   // nil if errs is empty
}
// Parallel operations · collect all failures
func fetchAll(ctx context.Context, urls []string) error {
    var mu sync.Mutex
    var errs []error
    var wg sync.WaitGroup
    for _, url := range urls {
        wg.Add(1)
        go func(u string) {
            defer wg.Done()
            if err := fetch(ctx, u); err != nil {
                mu.Lock()
                errs = append(errs, fmt.Errorf("%s: %w", u, err))
                mu.Unlock()
            }
        }(url)
    }
    wg.Wait()
    return errors.Join(errs...)
```

```
}
```

---

9. Enterprise Error Handling Strategy

Errors flow **up** through layers, gaining context. Logged **once** at the top.

```
.....................................................................
·  HANDLER · Maps domain errors · HTTP codes, logs ONCE            ·
·                                                                   ·
·  user, err := h.service.GetUser(ctx, id)                          ·
·  if err != nil { h.handleError(w, err); return }                  ·
.....................................................................
                                 ·
.....................................................................
·  SERVICE · Wraps with business context, does NOT log             ·
·                                                                   ·
·  user, err := s.repo.FindByID(ctx, id)                            ·
·  if err != nil { return nil, fmt.Errorf("get user %d: %w", id, err)
}
.....................................................................
                                 ·
.....................................................................
·  REPOSITORY · Translates DB errors · domain errors               ·
·                                                                   ·
·  if errors.Is(err, sql.ErrNoRows) {                               ·
·      return nil, fmt.Errorf("user %d: %w", id, ErrNotFound)       ·
·  }                                                                ·
.....................................................................
```

Error Mapping at the Handler

```
func (h *Handler) handleError(w http.ResponseWriter, err error) {
    h.logger.Error("request failed", "error", err)   // log FULL
chain ONCE
    switch {
    case errors.Is(err, ErrNotFound):
        http.Error(w, "resource not found", http.StatusNotFound)
    case errors.Is(err, ErrPermission):
        http.Error(w, "forbidden", http.StatusForbidden)
    default:
        http.Error(w, "internal server error",
http.StatusInternalServerError)
    }
}
```

The Error Chain Tells the Full Story

```
err.Error(): "get user 42: user 42: not found"
errors.Is(err, ErrNotFound) walks:
  wrapError{"get user 42: user 42: not found"}
    · Unwrap() · wrapError{"user 42: not found"}
```

```
      · Unwrap() · errorString{"not found"} · IS ErrNotFound ·
The chain answers: WHAT (not found) + WHERE (user 42, repo,
service)
```

The Golden Rules

```
1. WRAP at every layer     · fmt.Errorf("context: %w", err)
2. TRANSLATE at boundaries · sql.ErrNoRows · ErrNotFound
3. LOG once at the top     · handler/middleware only
4. MAP to status codes     · handler only, using errors.Is/As
5. SANITIZE for clients    · never expose internal error messages
```

---

10. Panic and Recover

`panic()` is for **truly unrecoverable** situations · programmer errors, not runtime conditions.

```
// YES · valid panic (bug in code, detected at init)
func MustCompile(pattern string) *regexp.Regexp {
    re, err := regexp.Compile(pattern)
    if err != nil { panic(fmt.Sprintf("invalid regex %q: %v",
pattern, err)) }
    return re
}
// NO · return an error (expected runtime condition)
func ReadConfig(path string) (*Config, error) {
    data, err := os.ReadFile(path)
    if err != nil { return nil, fmt.Errorf("read config %s: %w",
path, err) }
    // ...
}
```

Stack Unwinding

```
  CALL STACK (growing down)        PANIC UNWIND (going back up)
  .........................        ............................
  main()                           · main: deferred (defer runs)
    ·                              · panic continues up
    ·· levelOne()                  · one: deferred  (defer runs)
    ·    ·                         · panic continues up
    ·    ·· levelTwo()             · two: deferred  (defer runs)
    ·    ·    ·                    · panic("broke") · starts here
    ·    ·    ·· PANIC ............
```

Defers run in LIFO order during unwind. If no `recover()` is found, program crashes.

`recover()` · Catching a Panic

Only works **inside a deferred function**. This is Go's equivalent of try/catch.

```
func safeOperation() (err error) {
    defer func() {
        if r := recover(); r != nil {
```

```
            err = fmt.Errorf("panic recovered: %v", r)
        }
    }()
    riskyCode()
    return nil
}
```

Why `recover()` MUST Be Inside `defer`

When `panic()` fires, execution **jumps** · lines after the panic never runThe **only** code that executes during a panic unwind is **deferred functions**.

```
func broken() {
    recover()        // · useless · normal execution, no panic is
happening
    riskyCode()      // panic here · stack starts unwinding
    recover()        // · never reached · we already panicked past this
line
}
func works() {
    defer func() {
        recover()    // · runs during unwind · catches the panic
    }()
    riskyCode()      // panic here · defer runs, recover() catches it
}
```

Why the Anonymous Function?

`defer` needs a **function call**. You can't write meaningful recovery without one:

```
defer recover()           // · recovers but throws away the value ·
can't log, can't set err
defer fmt.Println("bye")  // · valid but only one statement · can't do
recovery logic
defer func() {            // · anonymous function lets you:
    r := recover()        //    1. capture the panic value
    err = fmt.Errorf(...) //    2. assign to the named return
    log.Error(...)        //    3. log it
    metrics.Inc(...)      //    4. record metrics
}()                       //    · note the () · you're CALLING the
function
```

How Named Returns Make This Work

The critical question: **how does the defer set the return value without a `return` statement?**

Named return values are the answer. With `(err error)` in the signature, `err` is not a local variable · it IS the **return slot** on the stack frame:

```
Stack frame of safeOperation:
.........................
·  return slot: err error  ·  · allocated at function entry, initialized
to nil
.........................
```

```
·  local variables...      ·
.........................
```

The deferred closure **captures** `err` · the same memory location as the return slotWriting to `err` inside the defer directly modifies what the caller will receive:

```
func safeOperation() (err error) {       // return slot: err = nil
    defer func() {                        // closure captures &err
(the return slot)
        if r := recover(); r != nil {
            err = fmt.Errorf("panic: %v", r)  // writes directly to
the return slot
            // NO return needed · we're modifying the slot, not a
local copy
        }
    }()
    riskyCode()    // PANIC! · defer runs · recover · err = error ·
function exits
    return nil     // never reached on panic path
}
// function exits · caller reads the return slot · finds the error we
wrote
```

Step-by-step trace · panic path:

```
· func safeOperation() (err error)    · return slot allocated, err =
nil
· defer func() { ... }()              · anonymous function registered
(not run yet)
· riskyCode()                         · PANIC! stack starts unwinding
· defer fires                         · anonymous function runs
· r := recover()                      · catches panic, r = the panic
value
· err = fmt.Errorf("panic: %v", r)   · writes error to return slot
· function exits                      · caller reads return slot · gets
the error
```

Step-by-step trace · happy path:

```
· func safeOperation() (err error)    · return slot allocated, err =
nil
· defer func() { ... }()              · registered
· riskyCode()                         · completes normally
· return nil                          · writes nil to return slot
· defer fires                         · recover() returns nil · if block
skipped
· function exits                      · caller reads return slot · gets
nil
```

This would NOT work without named returns:

```
func broken() error {           // unnamed return · no variable to
reference
    defer func() {
        if r := recover(); r != nil {
            // HOW do I set the return value?
```

```
            // There's no variable name to write to.
            // I can't "return" from inside a defer · return exits
the DEFER, not the outer func.
        }
    }()
    riskyCode()
    return nil
}
```

The Java parallel:

```
Java:   try { riskyCode(); } catch (Exception e) { return new
Error("recovered: " + e); }
Go:     defer func() { if r := recover(); r != nil { err =
fmt.Errorf("recovered: %v", r) } }()
```

Both achieve the same result. Go is more explicit · no hidden control flow, the recovery mechanism is visible as a deferred function call.

Production rule: You almost never call `recover()` in business logic. It belongs in:

1. **HTTP middleware** · recover panics so one bad request doesn't crash the server
2. **Goroutine launchers** · a panic in a goroutine kills the **entire program**, not just that goroutine

HTTP Recovery Middleware

```
func RecoveryMiddleware(next http.Handler) http.Handler {
    return http.HandlerFunc(func(w http.ResponseWriter, r
*http.Request) {
        defer func() {
            if rec := recover(); rec != nil {
                slog.Error("panic recovered", "panic", rec,
                    "stack", string(debug.Stack()), "path",
r.URL.Path)
                http.Error(w, "internal server error", 500)
            }
        }()
        next.ServeHTTP(w, r)
    })
}
```

---

11. Error Handling Anti-Patterns

(a) Swallowing Errors

```
result, _ := doSomething()            // BAD · silent failure
result, err := doSomething()           // FIX · handle it
if err != nil { return fmt.Errorf("do something: %w", err) }
```

(b) Logging AND Returning

```
// BAD · logged at every layer = duplicate logs
```

```
log.Printf("failed: %v", err)
return nil, fmt.Errorf("get user: %w", err)
// FIX · wrap and return only; handler logs once
return nil, fmt.Errorf("get user %d: %w", id, err)
```

(c) Wrapping Without Context

```
return fmt.Errorf("%w", err)                    // BAD · adds nothing
return fmt.Errorf("repo: find user %d: %w", id, err)  // FIX · WHERE
+ WHAT
```

(d) Panic for Control Flow

```
panic("user not found")              // BAD · expected condition
return nil, ErrNotFound              // FIX · return error value
```

(e) Comparing Error Strings

```
if err.Error() == "connection refused" { }    // BAD · fragile
if errors.Is(err, ErrConnRefused) { }         // FIX · use sentinels
```

(f) Ignoring Close/Write Errors

```
defer f.Close()                      // BAD · buffered writes may be
lost
defer func() {                       // FIX · capture close error
    if cerr := f.Close(); cerr != nil && err == nil { err = cerr }
}()
```

Summary

```
.......................................................................
· Anti-Pattern              · Fix
·
.......................................................................
· _ = f()                   · Always handle or explicitly document why
·
· log + return              · Wrap and return; log once at top
·
· fmt.Errorf("%w", err)     · Add context: "layer: operation: %w"     ·
· panic for expected errors · Return error values
·
· err.Error() == "..."      · errors.Is() or errors.As()              ·
· defer f.Close()           · Capture and check close error
·
.......................................................................
```

---

12. Error Handling in Concurrent Code

Panics Don't Cross Goroutine Boundaries

```
main goroutine              child goroutine
..............              ................
main()                      func() {
  ·  defer func() {           panic("boom")
  ·    recover() · NEVER      ·
  ·    TRIGGERED!              ·
  ·  }()                     no recover · PROGRAM CRASH
  ·· go func()...
```

Always `recover()` inside every goroutine that might panic.

`errgroup.Group` · The Standard Pattern

```
g, ctx := errgroup.WithContext(ctx)
for _, url := range urls {
    g.Go(func() error { return fetch(ctx, url) })
}
return g.Wait()   // first error cancels ctx, waits for all to
finish
```

Channel-Based Error Collection (All Errors)

```
errCh := make(chan error, len(urls))
var wg sync.WaitGroup
for _, url := range urls {
    wg.Add(1)
    go func(u string) {
        defer wg.Done()
        if err := fetch(ctx, u); err != nil {
            errCh <- fmt.Errorf("%s: %w", u, err)
        }
    }(url)
}
go func() { wg.Wait(); close(errCh) }()
var errs []error
for err := range errCh { errs = append(errs, err) }
return errors.Join(errs...)
```

---

13. Performance Characteristics

Cost Table

```
.................................................................................
· Operation                     · Approx Cost · Why
         ·
.................................................................................
· errors.New("msg")             · ~50-80ns    · 1 heap alloc (errorString
struct)   ·
·                               · 1 alloc     · + iface construction
```

```
         .
.......................................................................
· fmt.Errorf("ctx: %w", err)   · ~200-400ns  · String formatting + 1 heap
alloc   ·
·                              · 1-2 allocs  · (wrapError struct with msg
+ err)   ·
.......................................................................
· errors.Is() · depth 1        · ~5-10ns     · Pointer comparison + type
assertion ·
·                              · 0 allocs    ·
         .
.......................................................................
· errors.Is() · depth N        · ~5-10ns × N · Linear walk: Unwrap + compare
each ·
·                              · 0 allocs    ·
         .
.......................................................................
· errors.As() · depth 1        · ~50-100ns   · Uses reflect.TypeOf
internally     ·
·                              · 0-1 allocs  ·
         .
.......................................................................
· errors.As() · depth N        · ~50-100ns×N · Reflection at each level +
Unwrap  ·
·                              · 0-1 allocs  ·
         .
.......................................................................
· panic + recover              · ~1-5µs      · Stack unwinding + deferred
func     ·
·                              · varies      · execution. 100-1000×
costlier      ·
.......................................................................
· Stack trace (debug.Stack())  · ~5-20µs     · Walks call stack, formats
PCs to   ·
·                              · many allocs · function names
         .
.......................................................................
```

Go Errors vs Exceptions

```
Java/C# Exception:                    Go Error:
.................                     .........
· Created: captures full stack trace  · Created: allocates a small
struct
  (~5-20µs, many allocations)           (~50-80ns, 1 allocation)
· Thrown: unwinds the call stack      · Returned: normal function
return
  (walks frames, runs finally)          (register/stack copy, ~1ns)
· Caught: exception table lookup      · Checked: if err != nil (~0.5ns)
Go errors are 25-100× cheaper than Java exceptions.
```

Happy Path Is Free

The CPU branch predictor learns `err != nil` is almost always `false`. The nil pointer comparison is essentially free. Error creation cost only matters on failure.

---

14. Quick Reference Card

Decision Tree

```
You need to signal an error condition
·
·· Known condition callers must check?
·   ·· Simple (not found, timeout) · Sentinel: var ErrX =
errors.New("...")
·   ·· Needs data (field, code)    · Custom type: type XError struct{...}
·
·· Adding context to existing error? · fmt.Errorf("context: %w", err)
·· Combining multiple errors?        · errors.Join(err1, err2, ...)
·· Simple internal error?            · errors.New("description")
```

Checklist

```
· ALWAYS check returned errors        · DON'T log AND return
· WRAP with context at each layer     · DON'T compare error strings
· USE errors.Is/As not == or strings  · DON'T panic for expected errors
· TRANSLATE at boundaries             · DON'T wrap without adding
context
· LOG once at the top                 · DON'T export types unless
needed
· RECOVER panics in goroutines
· CHECK Close() errors for writers
```

Common Patterns

```
// Sentinel
var ErrNotFound = errors.New("not found")
// Custom type
type ValidationError struct{ Field, Message string }
func (e *ValidationError) Error() string {
    return fmt.Sprintf("validation: %s · %s", e.Field, e.Message)
}
// Wrap, check, extract
return fmt.Errorf("service: get user %d: %w", id, err)
if errors.Is(err, ErrNotFound) { /* sentinel match */ }
var ve *ValidationError
if errors.As(err, &ve) { /* use ve.Field */ }
// Goroutine recovery
defer func() { if r := recover(); r != nil { log.Printf("recovered:
%v", r) } }()
// Safe close
defer func() { if cerr := f.Close(); cerr != nil && err == nil {
err = cerr } }()
```

Tools

```
go vet ./...                    # common error handling mistakes
go build -gcflags='-m' ./...    # escape analysis: error alloc
locations
errcheck ./...                  # finds unchecked error returns
go test -race ./...             # race detector: always run
```

One-Line Summary

An `error` is a one-method interface (`Error() string`) stored as `iface{tab, data}` · wrapping with `%w` builds a linked chain walked by `errors.Is`/`errors.As`, sentinels define API contracts checked by value, custom types carry structured data extracted by type, and production code wraps at every layer, translates at boundaries, and logs once at the top.

Deep Dive: Concurrent Error Patterns · From Goroutines to errgroup

This document builds up from goroutine/channel basics to production-grade concurrent error handling patterns. Read this BEFORE doing the goroutine and channel exercises if you want to understand the "why" behind each pattern.

8 When to Use Which Pattern
9 Common Mistakes and Gotchas

---

1. Goroutines · The 30-Second Refresher

A goroutine is a lightweight thread managed by the Go runtime (~2-8KB stack vs ~1MB OS thread).

```
// Normal function call · blocks until done:
result := doWork()       // current goroutine waits here
// Goroutine · fires and continues immediately:
go doWork()              // launches new goroutine, current
goroutine moves to next line
fmt.Println("I don't wait")   // runs immediately, doWork() runs
concurrently
```

The critical mental model: `go doWork()` is fire-and-forget. The launching goroutine does NOT wait. It does NOT get a return value. It just keeps going.

```
Timeline:
  main goroutine:   [launch doWork] · [print "I don't wait"] · [exit
program]
  doWork goroutine: [starts]·····••••••••• [doing work]••• [maybe finishes... or
maybe main exits first]
```

Problem #1: If `main()` exits, ALL goroutines are killed immediately. No cleanup.

---

2. The Problem: Goroutines Can't Return Errors

This is the fundamental issue that all patterns below solve.

```
// Normal function · caller gets the error:
err := fetchURL("https://example.com")
if err != nil { /* handle it */ }
// Goroutine · WHERE does the error go?
go fetchURL("https://example.com")   // returns error to... nobody
// The error is created, returned, and silently garbage collected.
// The main goroutine has no idea anything went wrong.
```

Why? Because `go func()` is syntactic sugar for "launch this function on a new goroutine." There's no wire connecting the new goroutine back to the launching one. They're independent.

To get results (or errors) back from a goroutine, you need a communication mechanism. Go gives you two:

1. **Channels** · send values between goroutines (Go's preferred way)
2. **Shared memory + mutex** · write to a shared variable with lock protection

---

3. Channels · The Communication Pipe

A channel is a typed pipe between goroutines. One goroutine sends, another receives.

```
ch := make(chan string)    // create a pipe that carries strings
// Goroutine A: sends a value INTO the pipe
go func() {
    ch <- "hello"          // send · blocks until someone receives
}()
// Goroutine B (main): reads a value FROM the pipe
msg := <-ch                // receive · blocks until someone sends
fmt.Println(msg)           // "hello"
```

Visual:

```
Goroutine A                    Channel                    Goroutine
B (main)
                            .............
  ch <- "hello"  ••••••••• ·  "hello"  · •••••••••  msg := <-ch
                            .............
  (blocks until             (the pipe)              (blocks until
   receiver ready)                                   sender sends)
```

Buffered vs Unbuffered

```
// Unbuffered · sender blocks until receiver is ready (synchronous
handoff):
ch := make(chan string)
// Buffered · sender can put N items without blocking (like a mailbox
with N slots):
ch := make(chan string, 5)    // 5 slots · can send 5 times without a
receiver
```

Closing a Channel

```
close(ch)    // signals "no more values will be sent"
// Receivers can detect closure:
val, ok := <-ch    // ok=false means channel is closed and empty
// OR use range (reads until channel is closed):
for val := range ch {
    fmt.Println(val)    // processes each value, exits loop when ch
is closed
}
```

Error Channel · The Key Idea

Since channels carry typed values, they can carry `error`:

```
errCh := make(chan error, 1)    // a pipe that carries errors
go func() {
    err := riskyOperation()
    errCh <- err                // send error (or nil) back to main
}()
err := <-errCh                  // main waits here, receives the
error
if err != nil { /* handle */ }
```

This is how goroutines communicate errors back. The channel is the wire.

---

4. sync.WaitGroup ·"Wait for Everyone to Finish"

WaitGroup solves Problem #1: "main exits before goroutines finish."

It's a counter:

- `wg.Add(1)` · increment "one more goroutine to wait for"
- `wg.Done()` · decrement "one goroutine finished"
- `wg.Wait()` · block until counter reaches 0

```
var wg sync.WaitGroup
for i := 0; i < 3; i++ {
    wg.Add(1)                   // counter: 1, 2, 3
    go func(id int) {
        defer wg.Done()         // counter: 2, 1, 0 (when each
finishes)
```

```
        fmt.Println("worker", id)
    }(i)
}
wg.Wait()                     // blocks here until counter = 0
fmt.Println("all done")       // only runs after ALL goroutines
finish
```

Visual timeline:

```
main:      [Add 1][Add 1][Add 1]··————————————[Wait...]··————————————[all done]
worker 0:        [start]··[work]··[Done]                    ·
worker 1:              [start]··[work]·————·[Done]          · counter hits
0
worker 2:                    [start]··[work]··[Done]————————
```

Important: `defer wg.Done()` is the first line inside the goroutine · it ensures Done() runs even if the goroutine panics. Without defer, a panic skips Done(), and `wg.Wait()` blocks forever (deadlock).

---

5. Pattern 1: WaitGroup + Mutex (Collect All Errors)

The simplest pattern: shared `[]error` slice protected by a mutex.

```
func fetchAll(urls []string) error {
    var (
        wg   sync.WaitGroup
        mu   sync.Mutex       // protects the errs slice
        errs []error
    )
    for _, url := range urls {
        wg.Add(1)
        go func(u string) {
            defer wg.Done()
            if err := fetch(u); err != nil {
                mu.Lock()                                   //
lock before writing
                errs = append(errs, fmt.Errorf("%s: %w", u, err))
                mu.Unlock()                                 //
unlock after writing
            }
        }(url)
    }
    wg.Wait()                  // wait for ALL goroutines to finish
    return errors.Join(errs...)  // combine into single error (nil
if errs is empty)
}
```

Why the mutex? Multiple goroutines run concurrently. If two goroutines `append` to `errs` at the same time without a lock, you get a **data race** · corrupted memory, wrong values, or a crash. The mutex ensures only one goroutine writes at a time.

Step-by-step trace (3 URLs, URL #2 fails):

```
main:       [Add 1][Add 1][Add 1]————————————————————[Wait...]···[Join errs]
goroutine 1:      [fetch url1]———— OK ————[Done]            ·
```

```
goroutine 2:            [fetch url2]·· FAIL ··[Lock][append
err][Unlock]··[Done]  ·
goroutine 3:                  [fetch url3]···· OK ····[Done]·................
```

Pros: Simple, collects ALL errors. **Cons:** All goroutines run to completion even if one fails · no cancellation.

---

6. Pattern 2: Channel-Based Error Collection

Instead of a shared slice + mutex, send errors through a channel.

```
func fetchAll(ctx context.Context, urls []string) error {
    errCh := make(chan error, len(urls))    // buffered: won't
block senders
    var wg sync.WaitGroup
    // Launch all goroutines
    for _, url := range urls {
        wg.Add(1)
        go func(u string) {
            defer wg.Done()
            if err := fetch(ctx, u); err != nil {
                errCh <- fmt.Errorf("%s: %w", u, err)    // send
error into channel
            }
        }(url)
    }
    // Close channel AFTER all goroutines finish (in a separate
goroutine)
    go func() {
        wg.Wait()        // wait for all workers
        close(errCh)     // signal: no more errors will be sent
    }()
    // Collect all errors from the channel
    var errs []error
    for err := range errCh {    // reads until channel is closed
        errs = append(errs, err)
    }
    return errors.Join(errs...)
}
```

Let's break down the tricky parts:

Why `make(chan error, len(urls))`?

The buffer size `len(urls)` guarantees no goroutine will block on send. In the worst case, ALL URLs fail · that's `len(urls)` errors. With a buffer that large, every goroutine can send its error and call `Done()` without waiting for a receiver.

Without the buffer (or with a too-small buffer), a goroutine trying to send on a full channel blocks · and if the receiver isn't reading yet, you get a deadlock.

Why the separate `go func() { wg.Wait(); close(errCh) }()`?

This is the coordination trick. We need two things to happen:

1. **All goroutines must finish** before we close the channel
2. **The main goroutine must read from the channel** until it's closed

These can't happen on the same goroutine · the `for range errCh` loop blocks waiting for the channel to close, and `wg.Wait()` blocks waiting for goroutines to finish. If both are on main, main is stuck in `for range` and can never call `wg.Wait()`.

Solution: put `wg.Wait() + close()` on a separate goroutine:

```
main goroutine:           [launch workers]··[for range errCh...
reading errors...]··[done]
closer goroutine:         [wg.Wait()... waiting for
workers...]··[close(errCh)]···  ·

signals main ····
worker goroutines:        [fetch]··[send err if failed]··[Done]
```

Why `for err := range errCh`?

`range` over a channel reads values one at a time until the channel is **closed**. It's syntactic sugar for:

```
for {
    err, ok := <-errCh
    if !ok { break }           // channel closed, no more values
    errs = append(errs, err)
}
```

Pros: No mutex needed · channels handle synchronization. More "Go-idiomatic." **Cons:** More moving parts (the closer goroutine). Still no cancellation on first error.

---

7. Pattern 3: errgroup.Group (The Standard Pattern)

`errgroup` (from `golang.org/x/sync/errgroup`) combines WaitGroup + error collection + context cancellation into one clean API. **This is what you use in production.**

```
import "golang.org/x/sync/errgroup"
func fetchAll(ctx context.Context, urls []string) error {
    g, ctx := errgroup.WithContext(ctx)    // creates group +
derived context
    for _, url := range urls {
        g.Go(func() error {                // launches a goroutine
            return fetch(ctx, url)         // return error like a
normal function!
        })
    }
    return g.Wait()    // waits for ALL goroutines, returns FIRST
error
}
```

That's it. Three lines replace all the WaitGroup/mutex/channel boilerplate.

What `errgroup` Does Under the Hood

`errgroup.Group` is roughly this (simplified):

```
type Group struct {
    wg      sync.WaitGroup
    err     error              // stores the FIRST error
    once    sync.Once          // ensures only first error is
captured
    cancel  context.CancelFunc // cancels context on first error
}
func (g *Group) Go(f func() error) {
    g.wg.Add(1)
    go func() {
        defer g.wg.Done()
        if err := f(); err != nil {
            g.once.Do(func() {     // only runs ONCE · captures first
error
                g.err = err
                if g.cancel != nil {
                    g.cancel()     // cancels the context · signals
other goroutines
                }
            })
        }
    }()
}
func (g *Group) Wait() error {
    g.wg.Wait()       // waits for ALL goroutines to finish
    return g.err      // returns the first error (or nil)
}
```

Step-by-Step Trace

```
g, ctx := errgroup.WithContext(ctx)
// g = new Group with cancel function
// ctx = child context that will be cancelled on first error
g.Go(func() error { return fetch(ctx, "url1") })    // launches
goroutine 1
g.Go(func() error { return fetch(ctx, "url2") })    // launches
goroutine 2
g.Go(func() error { return fetch(ctx, "url3") })    // launches
goroutine 3
return g.Wait()    // blocks until all three finish
```

Scenario: url2 fails first:

```
goroutine 1: [fetch url1]···============[ctx cancelled! · returns early]··[Done]
goroutine 2: [fetch url2]··FAIL··[once.Do: save err, cancel ctx]··[Done]
goroutine 3: [fetch url3]··========[ctx cancelled! · returns early]··[Done]
                                        ·
g.Wait():   [...waiting...]····================[all Done]··returns first error
```

Key behavior:

1. `g.Go()` launches a goroutine · you return `error` like a normal function
2. **First error** is captured via `sync.Once` · subsequent errors are discarded

3 **Context is cancelled** on first error · other goroutines can detect this via `ctx.Done()`
4 `g.Wait()` blocks until ALL goroutines finish (not just until first error)
5 Returns the first error, or nil if all succeeded

Why Context Cancellation Matters

When url2 fails and cancels the context, goroutines 1 and 3 can detect this IF they check `ctx`:

```
func fetch(ctx context.Context, url string) error {
    req, err := http.NewRequestWithContext(ctx, "GET", url, nil)
    // When ctx is cancelled, this request is immediately aborted
    // The goroutine doesn't waste time waiting for a response
    resp, err := http.DefaultClient.Do(req)
    if err != nil { return err }  // returns context.Canceled
    // ...
}
```

Without context-aware operations, the goroutines would run to completion even though we already know the overall operation failed. Context cancellation enables **fast failure**.

---

8. When to Use Which Pattern

```
.......................................................................
· Question                              · Pattern
     ·
.......................................................................
· Need ALL errors?                      · WaitGroup + Mutex +
errors.Join   ·
·                                       · OR Channel-based collection
    ·
.......................................................................
· Need FIRST error + cancel remaining?  · errgroup.WithContext
    ·
.......................................................................
· Need ALL errors + cancellation?       · Custom: channel + context
    ·
.......................................................................
· Simple fire-and-forget?               · WaitGroup alone (no errors)
    ·
.......................................................................
· Production service?                   · errgroup (95% of the time)
    ·
.......................................................................
```

In practice, `errgroup` covers 95% of concurrent error handling needs. Use the channel pattern when you genuinely need every error collected.

---

9. Common Mistakes and Gotchas

Mistake 1: Forgetting to close the channel

```
// BUG: for range errCh blocks FOREVER · nobody closes the channel
for err := range errCh {
    errs = append(errs, err)
}
```

Mistake 2: Closing channel from multiple goroutines

```
go func() {
    close(errCh)    // PANIC if two goroutines close the same
channel
}()
```

Only ONE goroutine should close a channel · typically the "closer" goroutine that waits for all senders to finish.

Mistake 3: Data race on shared slice without mutex

```
// BUG: multiple goroutines appending concurrently · data race
go func() { errs = append(errs, err1) }()
go func() { errs = append(errs, err2) }()
// Run with: go test -race · will flag this
```

Mistake 4: Not using context in goroutines

```
g, ctx := errgroup.WithContext(ctx)
g.Go(func() error {
    return fetch(url)        // · ignores ctx · won't cancel on first
error
    return fetch(ctx, url)   // · respects ctx · cancels when group
fails
})
```

Mistake 5: Panic in a goroutine kills the ENTIRE program

```
go func() {
    panic("oops")    // kills main() and ALL other goroutines · no
recovery
}()
```

A panic in a goroutine is NOT caught by `recover()` in the launching goroutine. Each goroutine needs its own `defer/recover` if panics are possible:

```
go func() {
    defer func() {
        if r := recover(); r != nil {
            log.Printf("goroutine panic: %v", r)
        }
    }()
    riskyCode()
}()
```

One-Line Summary

Goroutines can't return errors · use channels or shared memory to communicate them back, `sync.WaitGroup` to wait for completion, and `errgroup.Group` to combine both with automatic context cancellation in production code.

Deep Dive: Goroutine Scheduler Internals · The GMP Model

How Go multiplexes millions of goroutines onto OS threads: the G-M-P model, work stealing, preemption, syscall handling, and the network poller.

1. Goroutines vs OS Threads

Go doesn't map one goroutine to one OS thread. It uses **M:N scheduling** · multiplexing M goroutines onto N OS threads.

```
.....................................................................
·                     Goroutine vs OS Thread                        ·
.....................................................................
· Property          · OS Thread        · Goroutine                 ·
.....................................................................
· Stack size        · ~1-8 MB (fixed)  · ~2-8 KB (growable)        ·
· Creation cost     · ~1-10 ·s         · ~0.3 ·s                   ·
· Context switch    · ~1-5 ·s (kernel) · ~100-200 ns (user-space)  ·
· Scheduling        · Kernel (OS)      · Go runtime (user-space)   ·
· Memory per 10k    · ~10-80 GB        · ~20-80 MB                 ·
· Max practical     · ~10k per process · Millions                  ·
· Identity          · OS thread ID     · goid (not exposed)        ·
.....................................................................
```

Why Is a Context Switch Cheaper?

An OS thread context switch requires:

- Trap into kernel mode (ring 3 · ring 0)
- Save/restore all CPU registers, FPU state, TLB
- Kernel scheduler decision
- Return to user mode

A goroutine context switch only:

- Saves ~15 registers into `g.sched` (a `gobuf` struct)
- Updates a few pointers (current G on current M)
- Stays entirely in user space · no kernel involvement

```
OS Thread Switch:                    Goroutine Switch:
............                        ............
· User     · ·· save regs           · Save     · ·· ~15 registers
· · Kernel · ·· kernel scheduler    · · Update · ·· swap G pointer
· · User   · ·· restore regs       · · Run    · ·· restore regs
............                        ............
~1-5 ·s                              ~100-200 ns
```

---

2. The GMP Model

The scheduler is built on three core entities:

```
G = Goroutine      (the unit of work)
M = Machine         (OS thread that executes code)
P = Processor       (scheduling context with a run queue)
```

The Relationship

```
                          ...............................
                          ·       Go Process            ·
                          ·                             ·
...........   ....................   ...........      ·
·    P0   ·   ·       P1        ·   ·    P2   ·      ·
· ....... ·   ·  .......        ·   · ....... ·      ·
· · LRQ · ·   ·  · LRQ ·        ·   · · LRQ · ·      ·
· ·G G G· ·   ·  ·G G  ·        ·   · ·G    · ·      ·
· ....... ·   ·  .......        ·   · ....... ·      ·
·    ·    ·   ·     ·           ·   ·    ·    ·      ·
·    M0   ·   ·     M1          ·   ·    M2   ·      ·
· (thread)·   ·  (thread)       ·   · (thread)·      ·
...........   ....................   ...........      ·
     ·              ·                     ·             ·
     ·      ..................            ·             ·
     ·      ·  Global Run    ·            ·             ·
     ·      ·  Queue (GRQ)   ·            ·             ·
     ·      ·  G G G G G     ·            ·             ·
     ·      ..................            ·             ·
     ....................................               ·
```

```
                                  .                               .
                                  ................................
```

Key rules:

- A G must be assigned to a P's run queue to execute
- A P must be attached to an M to run goroutines
- An M without a P is idle (parked or in syscall)
- Number of Ps = `GOMAXPROCS` (default: CPU core count)
- Number of Ms can exceed Ps (threads blocked in syscalls)

Source: `runtime/runtime2.go`, `runtime/proc.go`

---

3. The `runtime.g` Struct · Goroutine

Each goroutine is represented by a `runtime.g` struct (~400 bytes).

```
// runtime/runtime2.go (simplified)
type g struct {
    stack       stack        // lo, hi · current stack bounds
    stackguard0 uintptr     // compared with SP for stack growth
check
    m           *m           // the M currently running this G (nil
if not running)
    sched       gobuf        // saved registers for context switch
    atomicstatus atomic.Uint32 // goroutine state
    goid         uint64      // goroutine ID (not exposed to user
code)
    preempt      bool        // preemption signal
    // ... many more fields
}
type gobuf struct {
    sp   uintptr  // stack pointer
    pc   uintptr  // program counter (instruction pointer)
    g    guintptr // pointer back to this G
    ret  uintptr  // return value
    bp   uintptr  // base pointer (for frame pointer unwinding)
    // ... context, lr on ARM
}
```

Goroutine States

```
                    ............
             ......... _Gidle   · (just allocated, not yet used)
             .       ............
             .            · newproc()
             .            .
             .       ............  ··· schedule() picks this G
             .  ......_Grunnable...............................
             .  .    ............                              .
             .  .         · execute()                           .
             .  .         .                                     .
             .  .    ............                              .
```

```
·  ·    ·_Grunning · ··· G is executing on an M   ·
·  ·    ............                              ·

·     ............
·          · reused by newproc()
............
```

---

4. The `runtime.p` Struct · Processor

P is the **scheduling context**. It holds the local run queue and per-P resources.

```
// runtime/runtime2.go (simplified)
type p struct {
    id          int32
    status      uint32       // _Pidle, _Prunning, _Psyscall,
_Pgcstop, _Pdead
    m           muintptr     // the M currently attached to this P
    mcache      *mcache      // per-P memory cache (no lock
needed!)
    // Local run queue (LRQ) · lock-free circular buffer
    runqhead uint32
    runqtail uint32
    runq     [256]guintptr   // fixed-size array of 256 G pointers
    runnext  guintptr        // next G to run (fast path, skip
queue)
    // Timers (time.After, time.Sleep, etc.)
    timers   timers
    // GC state
    gcBgMarkWorker guintptr
    // ... more fields
```

```
}
```

The Local Run Queue (LRQ)

```
P.runq · circular buffer of 256 slots:
..................................... ... ........
·G12·G13·G14·G15·   ·   ·   ·   ·  ...       ·   ·
..................................... ... ........
 ^head              ^tail
 (next to dequeue)  (next to enqueue)
Operations:
- runqput():  enqueue G at tail (CAS, lock-free)
- runqget():  dequeue G from head (CAS, lock-free)
- runqsteal(): steal half from another P (CAS)
When LRQ is full (256 Gs):
· runtime moves HALF of the queue to the Global Run Queue (GRQ)
· this is called "overflow" · prevents one P from hoarding
```

The `runnext` Fast Path

`P.runnext` holds a single G that will be scheduled **next**, bypassing the queue. When `go func()` is called, the new goroutine is placed in `runnext` · this gives freshly created goroutines priority (good for producer-consumer patterns where the producer immediately creates work for the consumer).

Why P Exists (The Design Decision)

Before Go 1.1, there was no P · just G and M. Problems:

- Every goroutine operation required a global mutex on the run queue
- Memory caches were per-M, but Ms could be parked · cache wasted

P solves both: each P has a lock-free local queue and its own mcache. The global queue is only touched when a P overflows or is empty.

---

5. The `runtime.m` Struct · Machine

M represents an OS thread. The runtime creates Ms as needed.

```
// runtime/runtime2.go (simplified)
type m struct {
    g0        *g       // special goroutine for scheduling code
    curg      *g       // the user goroutine currently running
    p         puintptr // the P attached to this M (nil if no P)
    nextp     puintptr // P to attach on wakeup
    oldp      puintptr // P that was attached before syscall
    spinning  bool     // is this M looking for work?
    // ... thread ID, signal handling, etc.
}
```

The `g0` · Scheduler Stack

Every M has a special `g0` goroutine that runs scheduler code. When a goroutine needs to be scheduled (channel

block, syscall, preemption), execution switches from the user G's stack to `g0`'s stack to run `runtime.schedule()`.

```
Normal execution:         Scheduling:
.............             .............
· User G    ·             ·    g0     ·
· (your     · ··switch··· · (scheduler·
·  code)    ·             ·  code)    ·
· stack:    ·             · stack:    ·
· 2KB-1GB   ·             · ~8KB      ·
.............             .............
```

M Lifecycle

```
Need a new M?
·
·· Check sleeping M list (runtime.midle)
·   ·· Found? · wake it up, attach P · done
·
·· Not found? · create new OS thread (runtime.newm · pthread_create)
    ·· New M starts running runtime.mstart · schedule loop
```

The runtime doesn't eagerly create threads. It creates them on demand and reuses parked ones. There's a hard cap of 10,000 Ms by default (`runtime.SetMaxThreads()`).

---

6. Scheduling Algorithm

The core loop is `runtime.schedule()` · it runs on `g0`'s stack on every M.

```
runtime.schedule():
·
·· 1. Is there a runnext G on my P?
·      ·· YES · run it immediately (fast path)
·
·· 2. Check local run queue (P.runq)
·      ·· Non-empty · dequeue from head · run it
·
·· 3. Every 61st schedule call: check Global Run Queue (GRQ)
·      ·· Non-empty · grab a batch · run one
·      (61 is prime · avoids synchronization patterns)
·
·· 4. Check network poller (runtime.netpoll)
·      ·· Any goroutines ready from I/O? · grab them · run one
·
·· 5. Work stealing · steal from another P
·      ·· Pick random P · steal half its LRQ · run one
·
·· 6. Nothing anywhere?
       ·· Park this M (release P, go to sleep)
       ·· Will be woken when new work appears
```

Visual Flow

```
schedule() on M0/P0:
.............................................................
·  P0.runnext ··· G17 · RUN IT                              ·
·       ·                                                    ·
·       · (empty)                                            ·
·  P0.runq ··· [G3, G5, G8] · dequeue G3 · RUN IT        ·
·       ·                                                    ·
·       · (empty)                                            ·
·  Global Queue ··· [G20, G21, G22] · grab batch · RUN G20·
·       ·                                                    ·
·       · (empty)                                            ·
·  netpoll ··· [G30 (I/O ready)] · RUN G30                ·
·       ·                                                    ·
·       · (nothing)                                          ·
·  Steal from P2.runq ··· steal [G40, G41] · RUN G40      ·
·       ·                                                    ·
·       · (all Ps empty)                                     ·
·  Park M0 · (release P0, sleep until woken)              ·
.............................................................
```

---

7. Work Stealing

When a P's local queue is empty and the global queue is empty, the M enters **spinning** mode and tries to steal work from other Ps.

```
runtime.stealWork():
  1. Pick a random starting P (randomized to avoid thundering herd)
  2. For each P (round-robin from random start):
     a. Try to steal runnext · if success, done
     b. Try to steal half of P's runq · if success, done
  3. Check all Ps' timer heaps for expired timers
  4. If nothing found · give up, park M
  Stealing takes HALF the victim's queue:

  Before:
    P1.runq: [G1, G2, G3, G4, G5, G6]    P2.runq: []

  After steal:
    P1.runq: [G1, G2, G3]                 P2.runq: [G4, G5, G6]
```

Why Half?

Stealing half (not one, not all) balances load without excessive stealing overhead. If you steal one, you'll be back stealing again immediately. If you steal all, the victim starves.

Spinning Ms

The runtime limits the number of spinning Ms to avoid wasting CPU. At most `GOMAXPROCS` Ms can be spinning. A spinning M actively looks for work rather than parking · this reduces latency for newly created goroutines at the cost of CPU usage.

---

8. Preemption · Cooperative and Asynchronous

Cooperative Preemption (Pre-Go 1.14)

The compiler inserts a stack growth check at every function preamble:

```
; Function preamble (simplified)
MOVQ  (TLS), CX           ; load current G
CMPQ  SP, 16(CX)          ; compare SP with g.stackguard0
JLS   morestack           ; if SP < stackguard0 · grow stack /
preempt
```

To preempt a goroutine, the runtime sets `g.stackguard0 = stackPreempt` (a special value). At the next function call, the check triggers and the goroutine yields.

Problem: A tight loop with no function calls never hits the preamble check:

```
// This goroutine can NEVER be preempted (pre-Go 1.14):
go func() {
    for {
        i++  // no function calls · no preamble check · never yields
    }
}()
// Other goroutines starve on this P!
```

Asynchronous Preemption (Go 1.14+)

The runtime sends a **SIGURG** signal to the OS thread running the goroutine:

```
1. Scheduler decides G has run too long (~10ms sysmon check)
2. runtime.preemptM(mp) · sends SIGURG to thread M
3. Signal handler (sighandler) runs on M:
   a. Checks if G is at a "safe point" (no unsafe pointer ops)
   b. If safe · saves registers · sets preempt flag
   c. G is suspended · scheduler picks next G
4. If NOT at safe point · signal is noted, retry later
This works even in tight loops with no function calls!
```

Why SIGURG? It's an obscure signal that nothing else uses (it's for TCP out-of-band data, which Go's net package doesn't use). Safe to repurpose.

Windows: Uses `SuspendThread`/`GetThreadContext` instead of signals.

---

9. Syscall Handling · The Hand-Off

When a goroutine makes a blocking syscall (file I/O, CGo call), the M is blocked in kernel space. The P can't just wait · it hands off to another M.

```
Before syscall:
......     ......
· G5 · ··· · P0 · ··· M0 (running G5)
......     ......
G5 enters syscall (e.g., file read):
......     ......
· G5 · ··· ·    ·      M0 (blocked in kernel with G5)
```

```
      ......     · P0 ····   M3 (woken or created, takes over P0)
                 ......
      G5's syscall returns:
      M0 wakes up with G5
      ·· Try to reacquire P0 · if free, take it · continue
      ·· Try to get ANY idle P · if found, take it · continue
      ·· No P available · put G5 on Global Queue · M0 parks
```

The `sysmon` Thread

`runtime.sysmon` is a special M that runs **without a P** · it's a background monitor thread. It runs every 20·s-10ms and:

1. **Retakes Ps from syscalls**: if an M has been in a syscall for >20·s, sysmon steals its P and hands it to an idle M
2. **Preempts long-running Gs**: if a G has been running for >10ms, triggers preemption
3. **Polls the network**: calls `netpoll(0)` (non-blocking) to find ready I/O
4. **Triggers GC**: if needed based on heap growth

```
      sysmon (runs in a loop, no P needed):
      ....................................
      · for {                            ·
      ·   sleep(20·s · 10ms, adaptive)   ·
      ·   retake Ps from slow syscalls   ·
      ·   preempt long-running Gs       ·
      ·   poll network (non-blocking)    ·
      ·   trigger GC if needed           ·
      · }                                ·
      ....................................
```

---

10. Network Poller · Scalable I/O

Go wraps all network I/O with the runtime's integrated network poller, using OS-specific mechanisms:

```
      Linux:   epoll    (epoll_create, epoll_ctl, epoll_wait)
      macOS:   kqueue   (kqueue, kevent)
      Windows: IOCP     (CreateIoCompletionPort,
GetQueuedCompletionStatus)
```

How It Works

```
      1. G calls net.Read(conn) · data not ready
      2. runtime.pollWait() · register fd with epoll
      3. G state · _Gwaiting (parked, NO thread consumed)
      4. M detaches G, picks another G from P's queue
      ... later, data arrives on the socket ...
      5. sysmon calls runtime.netpoll() · epoll_wait returns fd
      6. Find the G parked on that fd
      7. G state · _Grunnable · enqueued on a P
      8. G resumes net.Read() with data ready
      Key insight: parked goroutine consumes ZERO thread resources
      · 100K concurrent connections = 100K goroutines, NOT 100K threads
```

Visual Flow

```
G1: net.Read()          G2: net.Read()       G3: computing
     .                       .                    .
     .                       .                    .
...........            ...........               .
· _Gwaiting·           ·_Gwaiting·               · running
· fd=42    ·           · fd=87   ·               · on M/P
............           ...........               .
     .                       .                    .
     ........................                     .
            .                                     .
      .............                               .
      ·  epoll    ·  (kernel watches fd 42, 87)   .
      ·  instance ·                               .
      .............                               .
            · fd 42 ready!                        .
            .                                     .
      G1 · _Grunnable · enqueued · runs          .
```

This is why Go excels at network-heavy services · the goroutine-per-connection model scales to hundreds of thousands of connections with minimal thread usage.

---

11. Stack Management

Contiguous Stacks (Go 1.4+)

Each goroutine starts with a **2KB stack** (since Go 1.4). Stacks are contiguous memory regions that grow and shrink dynamically.

```
Initial goroutine stack:
····................· high address (stack.hi)
·                   ·
·  (unused space)  ·   · only 2KB initially
·                   ·
····................· · SP (stack pointer)
·  current frame   ·
····................· low address (stack.lo)
```

Stack Growth

At every function preamble, the compiler inserts a check:

```
  1. Compare SP with g.stackguard0
  2. If SP < stackguard0 · stack is too small · call
runtime.morestack()
  3. morestack():
     a. Allocate new stack = 2x current size
     b. Copy entire old stack to new stack
     c. Update ALL pointers into the stack (scan and adjust)
     d. Free old stack
```

```
   e. Resume function on new stack

Before growth:                      After growth (2x):
............ 2KB                   ......................... 4KB
· frame 3  ·                       ·                       ·
· frame 2  ·      ··copy···        · frame 3               ·
· frame 1  ·                       · frame 2               ·
· frame 0  ·                       · frame 1               ·
............                       · frame 0               ·
                                   .........................
```

Stack Shrinking

During GC, if a goroutine's stack is less than 25% utilized, the runtime halves it (copies to a smaller allocation). This reclaims memory from goroutines that had deep call stacks temporarily.

Implications

- **Pointers to stack variables can move** · this is why you can't pass Go pointers to C code (CGo pins them to prevent movement)
- **Deep recursion has a hidden cost** · each growth copies the entire stack
- **Function calls are not free** · the preamble check adds ~1-2ns overhead (but enables preemption and growth)

---

12. Goroutine Lifecycle · Birth to Death

```
go myFunc(arg1, arg2)
```

Birth: `runtime.newproc()`

```
1. go myFunc(args) · compiler emits call to runtime.newproc()
2. newproc():
   a. Get a free G from P's local free list (gfget)
      ·· If none · allocate new runtime.g + 2KB stack
   b. Set up G's stack frame:
      - Copy function args onto G's stack
      - Set g.sched.pc = myFunc entry point
      - Set return address = runtime.goexit (cleanup stub)
   c. Set g.status = _Grunnable
   d. Put G on current P:
      - runqput(P, G) · tries runnext first, then LRQ
      - If LRQ full · move half to Global Queue
   e. If there's an idle P, wake an M to run it (wakep)
```

Running

```
schedule() picks G · execute(G):
1. Set g.status = _Grunning
2. Set M.curg = G, G.m = M
3. gogo(&g.sched) · restore registers from gobuf · jump to g.sched.pc
4. G's function executes on G's stack
```

Death: `runtime.goexit()`

```
  1. myFunc() returns · hits runtime.goexit() (planted as return
address)
  2. goexit():
     a. Set g.status = _Gdead
     b. Clear G's fields (m, stack references, etc.)
     c. Put G on P's free list (gfput) for reuse
     d. Call schedule() to find next G to run
```

Key insight: Goroutines are **recycled**, not freed. The `runtime.g` struct and its stack are reused for future `go` calls. This amortizes allocation cost.

---

13. GOMAXPROCS and Tuning

`GOMAXPROCS` sets the number of Ps · the maximum number of goroutines that can execute **simultaneously** on CPU.

```
  GOMAXPROCS = 4:
  ......  ......  ......  ......
  · P0 ·  · P1 ·  · P2 ·  · P3 ·   · 4 Ps, 4 goroutines run in parallel
  ......  ......  ......  ......
    .       .       .       .
   M0      M1      M2      M3      · 4 OS threads (at minimum)
```

Default Value

```
runtime.GOMAXPROCS(0)  // returns current value without changing
// Default: runtime.NumCPU() · number of logical CPU cores
```

In Containers

Problem: Inside a Docker container with `--cpus=2`, `runtime.NumCPU()` still returns the **host's** CPU count (e.g., 64). GOMAXPROCS is set too high · excessive context switching.

Solution: Use `go.uber.org/automaxprocs`:

```
import _ "go.uber.org/automaxprocs"
// Automatically reads cgroup CPU limits and sets GOMAXPROCS
correctly
```

Or set manually:

```
GOMAXPROCS=2 ./myservice  # match container CPU limit
```

When to Tune

```
.....................................................................
· Scenario                    · GOMAXPROCS recommendation          ·
.....................................................................
· CPU-bound work              · = number of cores (default)        ·
· I/O-bound work              · = number of cores (still default)  ·
· Container with CPU limit    · = container CPU limit              ·
```

```
· Reduce GC STW latency      · Higher can help (more GC workers)  ·
· Debugging / deterministic  · = 1 (forces sequential execution)  ·
.............................................................
```

---

14. Performance Characteristics

```
.......................................................................
· Operation               · Approx Cost  · What happens
·
.......................................................................
· go func() (create)      · ~0.3 ·s      · Get G from free list, setup
·
·                         ·              · stack, enqueue on P
·
.......................................................................
· Goroutine context       · ~100-200 ns  · Save/restore ~15 registers,
·
· switch                  ·              · swap G pointer on M
·
.......................................................................
· Channel send/recv       · ~50-300 ns   · Lock hchan + transfer +
·
· (see channel doc)       ·              · possible context switch
·
.......................................................................
· Syscall hand-off        · ~1-5 ·s      · Detach P from M, find/create
·
·                         ·              · new M, attach P
·
.......................................................................
· Stack growth (2x copy)  · ~1-10 ·s     · Allocate new stack, copy all
·
·                         ·              · frames, update pointers
·
.......................................................................
· Work steal              · ~0.5-2 ·s    · Lock victim P, copy half queue
·
.......................................................................
· Memory per goroutine    · ~2-8 KB      · Stack (2KB initial) + g struct
·
· (initial)               ·              · (~400 bytes)
·
.......................................................................
· 1M goroutines memory    · ~2-8 GB      · Mostly stack memory
·
.......................................................................
```

Practical Limits

- **Goroutine count:** Millions possible, but watch total memory. Use `runtime.NumGoroutine()` to monitor.

- **Thread count:** Defaults to max 10,000 (`runtime.SetMaxThreads()`). Hit when too many goroutines are blocked in syscalls simultaneously.
- **Stack size:** Each goroutine can grow to 1GB (default `runtime.SetMaxStack()`). In practice, deep recursion should be avoided.

---

15. Debugging Tools

`GODEBUG=schedtrace=N`

Prints scheduler state every N milliseconds:

```
GODEBUG=schedtrace=1000 ./myservice

SCHED 1004ms: gomaxprocs=4 idleprocs=2 threads=6 spinningthreads=1
  idlethreads=1 runqueue=0 [3 0 1 0]
          .          .          .          .          .           .. per-P LRQ
sizes
          .          .          .          .          .. global run queue size
          .          .          .          .. spinning Ms looking for work
          .          .          .. total OS threads created
          .          .. Ps with no work (idle)
          .. total Ps (GOMAXPROCS)
```

`GODEBUG=scheddetail=1`

Add per-goroutine detail (very verbose):

```
GODEBUG=schedtrace=1000,scheddetail=1 ./myservice
```

`go tool trace`

Visual timeline of all goroutine activity:

```
# Collect trace data
go test -trace=trace.out -bench=.
# Open in browser
go tool trace trace.out
```

Shows: goroutine creation/blocking/unblocking, GC phases, syscalls, network I/O, per-P timeline, and scheduling latency.

`runtime/pprof` · Goroutine Profile

```
import "runtime/pprof"
// Dump all goroutine stacks (goroutine leak detection)
pprof.Lookup("goroutine").WriteTo(os.Stdout, 1)
```

Or via HTTP:

```
import _ "net/http/pprof"
// GET /debug/pprof/goroutine?debug=1
```

Goroutine Leak Detection in Tests

```
func TestNoLeak(t *testing.T) {
    before := runtime.NumGoroutine()
    // ... run your code ...
    time.Sleep(100 * time.Millisecond) // let goroutines settle
    after := runtime.NumGoroutine()
    if after > before+1 {
        t.Errorf("goroutine leak: before=%d after=%d", before,
after)
    }
}
```

Or use `go.uber.org/goleak` for robust leak detection:

```
func TestMain(m *testing.M) {
    goleak.VerifyTestMain(m)
}
```

---

16. Quick Reference Card

```
GMP MODEL
.........
  G (goroutine)  · unit of work, ~2KB stack, runtime.g struct
  M (machine)    · OS thread, runs Gs, runtime.m struct
  P (processor)  · scheduling context, LRQ of 256 Gs, count =
GOMAXPROCS
  G needs P to run. P needs M to run. M without P is idle.
SCHEDULING ORDER
................
  P.runnext · P.runq (local) · Global Queue (every 61st) · netpoll · steal
GOROUTINE STATES
................
  _Grunnable · _Grunning · _Gwaiting (parked) · _Grunnable (woken)
  _Grunning · _Gsyscall · _Grunnable (syscall returned)
  _Grunning · _Gdead (function returned, recycled)
PREEMPTION
..........
  Cooperative: stack check at function preamble (all versions)
  Asynchronous: SIGURG signal at safe points (Go 1.14+)
  sysmon triggers preemption after ~10ms of running
SYSCALL HAND-OFF
................
  G enters syscall · P detached from M · P given to idle M
  Syscall returns · M tries to reacquire P · or G goes to global queue
NETWORK POLLER
..............
  net.Read() blocks · G parked, fd registered with epoll/kqueue/IOCP
  Data arrives · G made runnable · no thread consumed while waiting
STACK MANAGEMENT
................
  Initial: 2KB. Growth: 2x copy. Shrink: halved during GC if < 25%
used.
```

```
  Max: 1GB. Pointers into stack may move · can't pass to C.
TOOLS
.....
  GODEBUG=schedtrace=1000        scheduler state every second
  GODEBUG=scheddetail=1          per-goroutine detail
  go tool trace                  visual timeline
  runtime.NumGoroutine()         goroutine count
  go.uber.org/goleak             leak detection in tests
  go.uber.org/automaxprocs       container-aware GOMAXPROCS
```

One-Line Summary

Go's scheduler multiplexes goroutines (G) onto OS threads (M) through logical processors (P), using lock-free local run queues, work stealing for load balancing, async preemption via SIGURG, and an integrated network poller · enabling millions of goroutines on a handful of threads with ~200ns context switches.

Deep Dive: Goroutine Stacks · Contiguous Stacks, Growth, Shrinking & Pointer Adjustment

How Go manages per-goroutine stacks, why contiguous stacks replaced segmented stacks in Go 1.4, what happens when a stack grows, and why pointers into the stack must be adjusted.

---

1. Every Goroutine Gets Its Own Stack

When you write `go func() { ... }()`, the runtime allocates a new stack for that goroutine. This stack is **private** · no other goroutine can access it directly.

```
Process Memory
...............................................................
```

```
.                                                                  .
.  ............  ............  ............  ............  .
.  · G1 Stack ·  · G2 Stack ·  · G3 Stack ·  · G4 Stack ·  .
.  ·  2KB     ·  ·  8KB     ·  ·  2KB     ·  ·  32KB    ·  .
.  · (private)·  · (grew!)  ·  · (private)·  · (deep    ·  .
.  ·          ·  ·          ·  ·          ·  ·  recursion·  .
.  ............  ............  ............  ............  .
.       .              .            .              .         .
.       .              .            .              .         .
.  ...........................................................  .
.  ·              SHARED HEAP (one per process)          ·  .
.  ·  All goroutines can read/write heap objects          ·  .
.  ·  · channels, maps, slices, structs that escape      ·  .
.  ·  · GC scans and collects this memory                ·  .
.  ...........................................................  .
..............................................................
```

Key properties:

- **Initial size: 2KB** (since Go 1.4) · tiny compared to OS thread stacks (~1-8MB)
- **Heap-allocated**: the stack memory itself is allocated from the heap by the runtime
- **Growable**: up to a maximum (default 1GB, configurable via `runtime.SetMaxStack`)
- **Shrinkable**: GC can halve stacks that are <25% utilized
- **Private**: goroutine stacks are never shared · no locking needed for stack variables

Why 2KB? It's a deliberate trade-off. Small initial stacks let you create millions of goroutines without exhausting memory. An OS thread stack of 1MB × 1M goroutines = 1TB.A Go stack of 2KB × 1M goroutines = 2GB · feasible on modern machines.

---

2. Scope vs Stack Frame vs Stack · Three Different Things

A common misconception: "each scope gets its own stack." This is wrong. These are three entirely different concepts:

```
SCOPE        = compile-time visibility rule ("can I use this
variable name here?")
STACK FRAME  = runtime memory block for ONE function call
STACK        = the entire memory region for ONE goroutine (holds
ALL its frames)
```

One Goroutine = One Stack = Many Frames

Each **function call** pushes a new frame onto the goroutine's stack. Each **return** pops that frame. Scopes within a function do NOT create frames.

```
func main() {              // frame 1 pushed
    x := 10
    result := doWork(x)    // frame 2 pushed on top
    fmt.Println(result)
}
func doWork(n int) int {   // this IS a new frame
    temp := n * 2
    return helper(temp)    // frame 3 pushed on top
```

```
}
func helper(v int) int {   // this IS a new frame
    return v + 1
}

G1's single stack:
...............................  · stack top (high address)
·  main() frame               ·  · function call = new frame
·    x = 10                  ·
·    result = ???             ·
..............................
·  doWork() frame              ·  · function call = new frame
·    n = 10                  ·
·    temp = 20               ·
..............................
·  helper() frame              ·  · function call = new frame
·    v = 20                  ·  · SP points here
...............................  · stack bottom (low address, grows down)
When helper() returns · SP moves up, frame disappears
When doWork() returns · SP moves up again
```

Scopes Within a Function · Same Frame, Same Memory

```
func process() {
    a := 1                    // scope: function body
    if true {
        b := 2                // scope: if block
        _ = b
    }
    // b is NOT accessible here · compiler enforces this
    for i := 0; i < 3; i++ { // scope: for loop
        c := 3
        _ = c
    }
    // i, c are NOT accessible here · compiler enforces this
    _ = a
}
```

All variables live in the SAME stack frame:

```
process() frame (one flat block of memory):
...................................
·  offset 0:  a = 1              ·  · always allocated
·  offset 8:  b = 2              ·  · same frame! Not a new "scope stack"
·  offset 16: i = 0,1,2          ·  · same frame!
·  offset 24: c = 3              ·  · same frame!
...................................
Total frame size: 32 bytes, decided at COMPILE TIME.
The compiler knows exactly how much space all scopes need.
```

Scope is invisible to the runtime. The stack just sees a flat block of N bytes for the function. Whether `b` is in an `if` block or `c` is in a `for` loop doesn't matter · they're just offsets within the same frame.

Compiler Optimization: Slot Reuse for Non-Overlapping Scopes

The compiler can **reuse the same stack slot** for variables in non-overlapping scopes:

```
func example() {
    if condition {
        x := heavyCompute()   // x lives only in the if branch
        use(x)
    } else {
        y := otherCompute()   // y lives only in the else branch
        use(y)
    }
}

x and y are NEVER alive at the same time.
The compiler can assign them the same offset:
  offset 0: x OR y   · one slot, two names, depending on which branch
runs
Frame size: 8 bytes instead of 16. Less stack usage, better cache
behavior.
```

Loop Variables · Same Slot, Overwritten Each Iteration

```
for i := 0; i < 1000; i++ {
    temp := compute(i)
    use(temp)
}
```

`temp` occupies **one stack slot** reused across all 1000 iterations:

```
Iteration 0:  frame[offset 16] = compute(0)
Iteration 1:  frame[offset 16] = compute(1)   · same slot,
overwritten
Iteration 2:  frame[offset 16] = compute(2)   · same slot,
overwritten
...
```

Zero additional allocation. Zero stack growth. Just one memory location rewritten.

The Closure Capture Trap · Why This Matters

This is the most famous Go bug for newcomers, and it makes complete sense once you understand that loop variables are a single stack slot:

```
// BUG (pre-Go 1.22):
for i := 0; i < 5; i++ {
    go func() {
        fmt.Println(i)  // closure captures the ADDRESS of i
    }()
}
// Prints: 5 5 5 5 5  (not 0 1 2 3 4!)
```

Why? Under the hood:

```
for loop frame:
...............................
```

```
·  i  (at offset 0)           ·  · ONE slot, ONE address: 0xc000012000
...............................
Iteration 0: i = 0 at 0xc000012000. Closure captures ADDRESS
0xc000012000.
Iteration 1: i = 1 at 0xc000012000. Another closure captures SAME
address.
Iteration 2: i = 2 at 0xc000012000. Another closure captures SAME
address.
...
Loop ends:   i = 5 at 0xc000012000.
All 5 goroutines start running. They all read *0xc000012000 · they
all see 5.
```

The closure doesn't copy `i` · it captures a **pointer to i's stack slot** (this is called "capture by reference"). Since all closures point to the same slot, and the loop has already finished by the time goroutines execute, they all see the final value.

Source: `runtime/runtime2.go` · closures are implemented as `funcval` structs that contain pointers to captured variables. The compiler allocates captured variables on the heap (they escape!) so they survive the function return.

```
// What the compiler actually generates (simplified):
i := new(int)  // i escapes to heap because closure captures it
for *i = 0; *i < 5; (*i)++ {
    go funcval{fn: anonFunc, captured: [i]}()  // all share same
*int
}
```

The fix (pre-Go 1.22):

```
for i := 0; i < 5; i++ {
    i := i  // shadow with a NEW variable · gets its own stack slot
(or heap slot)
    go func() {
        fmt.Println(i)  // captures the shadow, not the loop
variable
    }()
}
// Prints: 0 1 2 3 4 (in some order)
```

Go 1.22 fix: The language changed loop variable scoping. Each iteration gets a **new variable** automatically. The compiler inserts the shadow for you.

```
// Go 1.22+: this now works correctly!
for i := 0; i < 5; i++ {
    go func() {
        fmt.Println(i)  // each iteration's i is a separate
variable
    }()
}
// Prints: 0 1 2 3 4 (in some order)
```

This was one of the most debated changes in Go's history. It broke backward compatibility for a tiny number of programs but fixed the most common Go bug. See: Go 1.22 Release Notes · Loop Variable Change

---

3. The History: Segmented Stacks (Go 1.0·1.3)

Before Go 1.4, Go used **segmented stacks** · a linked list of stack segments.

```
Segmented Stack (Go 1.0-1.3):
  Segment 1 (4KB)        Segment 2 (4KB)        Segment 3 (4KB)
  ................       ................       ................
  ·  main()      ·       ·  doWork()    ·       ·  deepCall()  ·
  ·  frame       .........  frame       .........  frame       ·
  ·              · link   ·              · link   ·              ·
  ................       ................       ................
```

The "Hot Split" Problem

Segmented stacks had a critical performance bug called the **hot split problem**:

```
func processItem(item Item) {  // this function needs more stack
than available
    // stack is almost full...
    buffer := make([]byte, 1024)  // needs new segment!
    process(buffer)
    // returns · segment is freed
}
for _, item := range items {
    processItem(item)  // EACH call: allocate segment · use · free ·
repeat
    // This loop creates and destroys a stack segment on EVERY
iteration!
}

Iteration 1: alloc segment · call processItem · return · free segment
Iteration 2: alloc segment · call processItem · return · free segment
Iteration 3: alloc segment · call processItem · return · free segment
... 1 million iterations · 1 million alloc/free cycles!
```

If a function call happens right at the stack boundary, every call causes a segment allocation, and every return frees it. In a tight loop, this turned into constant allocation/deallocation thrashing · sometimes **100x slowdown**.

This was unpredictable. Whether you hit the hot split depended on the exact stack usage, which varied by platform, compiler version, and inlining decisions. A seemingly innocent refactor could trigger it.

The Go Team's Decision

From the Go 1.4 release notes:

> *"Segmented stacks cause performance problems. We're switching to contiguous stacks, which are simpler and solve the hot split problem."*

The idea: instead of adding a new segment, **copy the entire stack to a bigger contiguous block**. More expensive per growth event, but growth events are rare (only when the stack actually needs more space), and there's no hot split.

---

4. Contiguous Stacks (Go 1.4+) · The Current Design

A contiguous stack is a single, unbroken block of memory. When it's full, the runtime allocates a new block **twice the size** and copies everything.

```
Before growth:                       After growth:
...................                 ........................................
·  main()          ·                ·  main()          (same data,
·
·    x := 42       ·                ·    x := 42        new address)
·
·    p := &x ···x  ·    COPY ·     ·    p := &x ···x  (pointer UPDATED!) ·
·  doWork()        ·                ·  doWork()
·
·    y := 10       ·                ·    y := 10
·
·    [FULL!]       ·                ·    needMore()     (room to grow)
·
...................                 ·                                      ·
   2KB at addr 0x1000               ·
    ·
                                    ·    (empty space for future
calls)    ·
                                    ........................................
                                       4KB at addr 0x5000
   Old 2KB block is freed.
```

Growth factor: always 2×

```
2KB · 4KB · 8KB · 16KB · 32KB · 64KB · ... · up to 1GB (default max)
```

---

5. Stack Growth · Step by Step

Source: `runtime/stack.go` · functions `newstack()` and `copystack()`

```
Step 1: DETECT · "Do I need more stack?"
........................................
  Every function (except leaf functions and nosplit) has a PREAMBLE
  inserted by the compiler:
    if SP < stackguard0 {    // SP = current stack pointer
        runtime.morestack()  // stackguard0 = "danger zone"
boundary
    }
  This check is ~1 CPU instruction (compare + conditional jump).
  In the hot path (stack is big enough), the branch is NOT taken.
  CPU branch predictor learns this quickly · near-zero overhead.
Step 2: ALLOCATE · "Get me a bigger stack"
........................................
  newsize := oldsize * 2
  newstack := stackalloc(newsize)  // allocate from stack pool or
heap
  Stack pools: the runtime maintains per-size free lists of
previously
  used stacks. If a 4KB stack was freed earlier, it can be reused
here.
```

```
  This avoids hitting the heap allocator for common sizes.
Step 3: COPY · "Move everything to the new stack"
...................................................
  memmove(newstack, oldstack, oldsize)
  This copies ALL frames, ALL local variables, ALL saved registers.
  It's a bulk memory copy · very fast for small stacks (2-8KB),
  measurable for large stacks (100KB+).
Step 4: ADJUST POINTERS · "Fix all references into the stack"
............................................................
  The stack has moved! Any pointer that pointed into the old stack
  now points to freed memory. The runtime MUST find and update
  every such pointer.
  delta := newstack_base - oldstack_base  // address offset
  Walk every stack frame:
    For each frame, consult the STACK MAP (compiler-generated
bitmap):
      For each pointer-sized slot that the bitmap says is a
pointer:
        if it points into the old stack range:
          *slot += delta   // adjust by the offset
  (See Section 5 for the full pointer adjustment algorithm)
Step 5: FREE OLD STACK
......................
  Return old stack to the stack pool (or free to heap if too
large).
Step 6: RESUME
..............
  The goroutine continues executing on the new stack.
  It doesn't know anything happened · all its variables are intact
  at new addresses, all pointers are updated.
```

How Often Does Growth Happen?

In practice, most goroutines grow their stack **0-3 times** during their lifetime:

```
Typical goroutine lifecycle:
  Start:      2KB  (enough for simple functions)
  First grow: 4KB  (if it calls a few functions)
  Maybe:      8KB  (if moderately deep call chain)
  Rare:       16KB+ (deep recursion or large stack frames)
```

The 2× growth factor means growth events decrease exponentially.After 2-3 growths, the stack is big enough for the goroutine's entire lifetime.

---

6. Pointer Adjustment · The Critical Step

This is the most subtle part of contiguous stacks. When the stack moves, every pointer **into** the old stack becomes dangling. The runtime must fix them all.

What Needs Adjustment?

```
NEEDS adjustment (points into the stack):
```

```
  - Local variable pointers:  p := &x  (where x is on the stack)
  - Slice headers pointing to stack arrays
  - Pointer arguments passed between stack frames
  - Saved frame pointers and return addresses
  - defer struct pointers
  - Pointers in the goroutine's g struct (stackbase, stackguard,
etc.)
Does NOT need adjustment (points to heap or static data):
  - Pointers to heap objects:  p := &User{}  (escaped to heap)
  - Pointers to global variables
  - Pointers to string literals
  - Function pointers
  - Interface data pointers (heap-allocated)
```

The Adjustment Algorithm

```
Given: old stack at [old_lo, old_hi)
       new stack at [new_lo, new_hi)
       delta = new_lo - old_lo
For each frame on the stack:
  1. Look up the function's stack map (compiled into the binary)
  2. The stack map is a bitmap: 1 bit per pointer-sized slot
     bit = 1 · this slot contains a pointer
     bit = 0 · this slot is a scalar (int, bool, etc.) · skip it
  3. For each slot marked as pointer:
     ptr := *slot
     if old_lo · ptr < old_hi:    // does it point into the OLD
stack?
         *slot = ptr + delta       // YES · adjust it
     // else: points to heap/static · leave it alone
Example:
  old_lo = 0x1000,  old_hi = 0x1800  (old 2KB stack)
  new_lo = 0x5000,  new_hi = 0x6000  (new 4KB stack)
  delta  = 0x4000
  Slot at frame offset 16 contains: 0x1010  (points into old
stack!)
    0x1010 is in [0x1000, 0x1800) · YES
    *slot = 0x1010 + 0x4000 = 0x5010  · now points to correct new
location
  Slot at frame offset 24 contains: 0xc000a4000  (points to heap)
    0xc000a4000 is NOT in [0x1000, 0x1800) · skip, leave as-is
```

Visual Example

```
OLD STACK (0x1000):                     NEW STACK (0x5000):
  main() frame:                          main() frame:
  ............................           ............................
  · x   = 42                · 0x1010     · x   = 42                · 0x5010
  · y   = 3.14              · 0x1018     · y   = 3.14              · 0x5018
  · p   = 0x1010 ··x  [PTR]· 0x1020     · p   = 0x5010 ··x  [ADJ]· 0x5020
  · str = "hello"      [HEAP]· 0x1028    · str = "hello"      [SAME]·
0x5028
  ............................           ............................
```

```
  · doWork() frame:         ·           · doWork() frame:         ·
  · buf = [0x1010]     [PTR]· 0x1040    · buf = [0x5010]     [ADJ]· 0x5040
  · n   = 100          [INT]· 0x1048    · n   = 100          [INT]· 0x5048
  · hp  = 0xc000a0  [HEAP] · 0x1050    · hp  = 0xc000a0  [SAME] · 0x5050
  ............................           ............................
  Stack map for main():    [0, 0, 1, 0]  · slot 2 (p) is a pointer
  Stack map for doWork():  [1, 0, 1]     · slot 0 (buf) and slot 2
(hp) are pointers
  Adjustment:
    p:   0x1010 · in old range · 0x1010 + 0x4000 = 0x5010 ·
    str: points to heap literal · NOT in old range · unchanged ·
    buf: 0x1010 · in old range · 0x1010 + 0x4000 = 0x5010 ·
    hp:  0xc000a0 · NOT in old range · unchanged ·
    n:   not a pointer (stack map says 0) · skipped ·
```

---

7. Stack Maps · How the Runtime Finds Pointers

The compiler generates a **stack map** for every function at every "safe point" (places where stack growth or GC can happen). Without stack maps, the runtime couldn't distinguish pointers from integers on the stack.

Source: `cmd/compile/internal/liveness/planner.go`

```
func doWork(p *int, n int, hp *User) {
    // p is a pointer, n is an int, hp is a pointer
    // The compiler generates a bitmap for this frame:
    // [1, 0, 1] = [pointer, scalar, pointer]
}
```

Where Stack Maps Are Stored

```
Binary layout:
.......................................
·  .text section (compiled code)       ·
·    func doWork(...)                  ·
·    func main(...)                    ·
·                                      ·
.......................................
·  .rodata section (read-only data)    ·
·    stack maps:                       ·
·      doWork: bitmap [1, 0, 1]        ·
·      main:   bitmap [0, 0, 1, 0]    ·
·      ...one per function per PC      ·
·                                      ·
·    Each function has a funcdata that ·
·    maps: PC offset · stack map index ·
·                                      ·
·    Same maps are used by GC to scan  ·
·    goroutine stacks for live pointers·
.......................................
```

Why Stack Maps Are Per-PC (Program Counter)

A function's live pointer set changes as it executes:

```
func example() {
    // PC=0: no pointers live on stack · bitmap: []
    x := 42
    // PC=1: still no pointers · bitmap: [0]
    p := &x
    // PC=2: p is a pointer · bitmap: [0, 1]
    doSomething()
    // PC=3: if p is no longer used, bitmap: [0, 0] · GC can ignore
it
}
```

The compiler tracks pointer liveness at each potential safe point and generates the appropriate bitmap. This is the same infrastructure used by the garbage collector to scan goroutine stacks.

---

8. Stack Shrinking · During GC

Stacks can also **shrink**. During garbage collection, the runtime checks each goroutine's stack utilization:

```
GC Stack Shrinking:
  1. During the mark phase, the GC scans each goroutine's stack
  2. It notes the stack's total size and how much is actually used
  3. If used < 25% of capacity:
       newsize = oldsize / 2
       Copy stack to smaller buffer (same pointer adjustment
process)
       Free old stack
Example:
  G1 grew its stack to 32KB during a deep call chain.
  Later, G1 is handling simple requests using only 4KB.
  GC sees: 4KB used / 32KB capacity = 12.5% < 25%
  · Shrink to 16KB. Next GC might shrink to 8KB.
```

Why shrink? Without shrinking, a goroutine that once needed 1MB for a deep recursive call would hold 1MB forever, even if it now only uses 4KB. In a server with 10K goroutines, that's 10GB wasted.

Trade-off: Shrinking too aggressively causes repeated grow-shrink cycles. The 25% threshold is a balance · shrink only when the waste is significant.

---

9. Stack Growth Detection · The Function Preamble

Every function (except `nosplit` functions) starts with a **stack check**:

```
; Assembly output (go build -gcflags='-S')
; Function preamble for doWork():
TEXT doWork(SB), $128     ; this function needs 128 bytes of stack
    MOVQ  (TLS), CX        ; CX = current goroutine (g)
    CMPQ  SP, 16(CX)       ; compare SP with g.stackguard0
    JLS   morestack         ; if SP < stackguard0: need more stack!
    ; ... normal function body ...
morestack:
```

```
    CALL  runtime.morestack_noctxt(SB)  ; grow the stack
    JMP   doWork(SB)                     ; restart the function

Stack layout with guard:
.............................  · stack top (high address)
·                           ·
·  (used frames)            ·
·                           ·
.............................  · SP (stack pointer, grows downward)
·                           ·
·  (remaining space)        ·
·                           ·
.............................  · stackguard0 (danger zone!)
·  guard area (small)       ·     If SP drops below here · grow
.............................  · stack bottom (low address)
```

Cost of the check: One COMPARE + one conditional JUMP. The branch predictor learns this is almost always "not taken" (stack is usually big enough), so the amortized cost is essentially **zero** in the hot path.

`//go:nosplit` · Skipping the Check

Some runtime functions use `//go:nosplit` to skip the stack check:

```
//go:nosplit
func fastPath() {
    // NO stack growth check here
    // This function MUST NOT call any function that might grow the
stack
    // Used in scheduler code, signal handlers, and other critical
paths
}
```

This is dangerous · if the function uses more stack than available, the program crashes with a stack overflow. Only the runtime team and very low-level code uses this.

---

10. Stacks and Channels · The Direct Copy Connection

Now you can see why the channel "direct send" path is so elegant:

```
Goroutine G1 (sender):             Goroutine G2 (receiver):
.......................            .......................
·  Stack (G1's own)    ·           ·  Stack (G2's own)    ·
·                     ·           ·                      ·
·  val := 42           · 0xA010   ·  v := <-ch           · 0xB020
·  ch <- val           ·           ·  (v is here, waiting ·
·                     ·           ·   for a value)       ·
.......................            .......................
         ·                                  ·
         ·     typedmemmove(&v, &val, 8)    ·
         ....................................
              Direct copy: G1's stack · G2's stack
```

This is safe because:

1. G2 is parked (sleeping) · its stack won't move during the copy
2. The sudog stores `elem = &v` · a direct pointer to G2's stack variable
3. The runtime holds `hchan.lock` · no concurrent modification
4. After the copy, G2 is woken and finds `v = 42` on its stack

What if G2's stack had grown between parking and receiving? It can't! A parked goroutine is not running · it can't call functions, so no stack growth check executes. The stack is frozen at the exact state it was in when the goroutine was parked. The sudog.elem pointer remains valid.

---

11. Performance Implications

Stack Growth Cost

```
.................................................................
· Operation                · Approximate Cost                  ·
.................................................................
· Stack check (no growth)  · ~0.5-1ns (branch predictor handles)  ·
· Stack growth (2KB·4KB)   · ~1-5·s (alloc + copy + adjust)       ·
· Stack growth (64KB·128KB)· ~10-50·s (larger copy + more ptrs)   ·
· Stack shrink (during GC) · ~1-10·s (same as growth)             ·
· Stack alloc from pool    · ~100ns (reuse freed stack)            ·
· Stack alloc from heap    · ~500ns-1·s (fresh allocation)         ·
.................................................................
```

When Stack Growth Hurts

Deep recursion is the main pain point:

```
func fibonacci(n int) int {
    if n <= 1 { return n }
    return fibonacci(n-1) + fibonacci(n-2)
}
fibonacci(40):
  - Call depth: up to 40 frames
  - Each frame: ~64-128 bytes
  - Total stack: ~5KB
  - Growth events: 2-3 (2KB · 4KB · 8KB)
  - Each growth copies the ENTIRE stack
fibonacci(10000):
  - Call depth: up to 10000 frames
  - Total stack: ~1MB
  - Growth events: ~10 (2KB · 4KB · ... · 2MB)
  - Later growths copy hundreds of KB!
  - Pointer adjustment walks thousands of frames
```

Solutions:

- Convert recursion to iteration (always preferred in Go)
- Use a manual stack (slice) for tree/graph traversal
- Pre-allocate goroutine stack size (not directly possible, but reducing initial call depth helps)

Why Go Prefers Iteration Over Recursion

Go does not have **tail call optimization** (TCO). In languages with TCO (Scheme, Erlang, some Scala), `return f(x)` reuses the current frame. Go deliberately chose NOT to implement TCO because:

1. Stack traces would lose information (frames are reused, not stacked)
2. defer semantics would be ambiguous (when does the deferred function run?)
3. The Go team values debuggability over micro-optimization

This means every recursive call in Go adds a frame · grows the stack · potential growth event. For hot-path code, always prefer iteration.

---

12. Debugging Stack Behavior

See Stack Size at Runtime

```
import "runtime/debug"
func printStackSize() {
    var buf [1]byte
    // The address of a local variable tells you roughly where SP
is
    fmt.Printf("approximate SP: %p\n", &buf)
}
// Or check goroutine count (indirect measure of total stack
memory):
fmt.Println("goroutines:", runtime.NumGoroutine())
```

Force Stack Growth (for Testing)

```
//go:noinline
func growStack(depth int) {
    var buf [1024]byte  // 1KB per frame
    buf[0] = byte(depth)
    if depth > 0 {
        growStack(depth - 1)  // each call adds ~1KB frame
    }
    _ = buf
}
// growStack(100) · forces stack to grow to ~100KB
```

See Stack Map in Assembly

```
go build -gcflags='-S' ./mypackage/ 2>&1 | grep -A5 "gclocals"
# gclocals entries show the stack map bitmaps for each function
```

Monitor Stack Memory with `runtime.MemStats`

```
var m runtime.MemStats
runtime.ReadMemStats(&m)
fmt.Printf("Stack in use: %d bytes\n", m.StackInuse)
fmt.Printf("Stack from OS: %d bytes\n", m.StackSys)
```

13. Quick Reference Card

```
GOROUTINE STACKS
................
  Initial size: 2KB (since Go 1.4)
  Growth: 2× each time (2KB · 4KB · 8KB · ...)
  Max size: 1GB default (configurable via runtime.SetMaxStack ·
runtime/debug)
  Shrink: during GC, halved if <25% used
  Private: each goroutine owns its stack, no sharing
CONTIGUOUS STACKS (Go 1.4+)
...........................
  Replaced segmented stacks to fix the "hot split" problem
  Growth = allocate 2× buffer · copy all frames · adjust pointers · free
old
  Pointer adjustment uses compiler-generated stack maps (bitmaps)
SCOPE vs FRAME vs STACK
.......................
  Scope = compile-time visibility rule (if/for/block boundaries)
  Frame = runtime memory for one function call (all scopes share
one frame)
  Stack = entire memory region for one goroutine (holds all frames)
  Scope does NOT create a frame. Only function calls create frames.
  Compiler may reuse slots for variables in non-overlapping scopes.
  Loop variable = one slot overwritten each iteration (not N
allocations)
CLOSURE CAPTURE TRAP
....................
  Closures capture variable ADDRESS, not value (capture by
reference)
  Loop var = one stack slot · all closures see final value
  Fix (pre-1.22): shadow with i := i inside loop
  Fix (Go 1.22+): language changed · each iteration gets new variable
STACK GROWTH DETECTION
......................
  Every function preamble: if SP < stackguard0 · call morestack
  Cost when no growth needed: ~0.5ns (branch predictor)
  //go:nosplit skips the check (dangerous, runtime-only)
POINTER ADJUSTMENT
..................
  delta = new_base - old_base
  For each frame · consult stack map bitmap:
    If slot is pointer AND points into old stack range:
      *slot += delta
  Same stack maps used by GC to scan stacks
STACK MAPS
..........
  Generated by compiler for every function at every safe point
  Bitmap: 1 = pointer, 0 = scalar
  Stored in binary's .rodata section
  Maps are per-PC (pointer liveness changes within a function)
```

```
PERFORMANCE
..........
  Stack check: ~0.5ns (branch predicted, nearly free)
  Stack growth: ~1-50·s depending on stack size
  Deep recursion: each growth copies more data · prefer iteration
  No tail call optimization in Go (by design · debuggability)
CHANNELS + STACKS
................
  Direct send: copies value from sender's stack to receiver's stack
  Safe because parked goroutine's stack is frozen (no growth
possible)
  sudog.elem = pointer directly into receiver's stack variable
TOOLS
.....
  runtime.NumGoroutine()              # goroutine count
  runtime.ReadMemStats(&m)            # m.StackInuse, m.StackSys
  go build -gcflags='-S'              # see stack check preamble in
assembly
  GODEBUG=schedtrace=1000             # scheduler trace (shows
goroutine counts)
  runtime/debug.SetMaxStack(bytes)    # configure max stack size
```

Key Takeaways

1. **Every goroutine has its own private stack (2KB initial, growable to 1GB).** Stacks are cheap · this is why you can have millions of goroutines.
2. **Contiguous stacks (Go 1.4+) fixed the hot split problem** of segmented stacks. Trade-off: growth is more expensive (must copy), but growth events are rare.
3. **Stack growth copies everything and adjusts all pointers.** The compiler generates stack maps (bitmaps) so the runtime knows which slots are pointers vs scalars.
4. **The heap is shared, stacks are private.** This is why heap access needs synchronization (mutexes/channels/atomics) but stack variables don't.
5. **Prefer iteration over recursion in Go.** No TCO means every recursive call adds a frame. Deep recursion causes repeated expensive stack growths.
6. **Channel direct send works because parked goroutines have frozen stacks.** The sudog stores a pointer directly into the receiver's stack · safe because the receiver can't grow its stack while parked.

> *"Goroutine stacks start small and grow as needed. This is central to Go's concurrency model · cheap goroutines enable the CSP style."* · Go runtime documentation

---

1. The Runtime Struct: `hchan`

When you write `make(chan int)` or `make(chan int, 5)`, the runtime allocates a `runtime.hchan` struct on the heap. A channel variable is always a pointer to this struct.

Source: `runtime/chan.go`

```
type hchan struct {
    qcount   uint           // current number of elements in the
buffer
    dataqsiz uint           // capacity of the circular buffer (0
for unbuffered)
    buf      unsafe.Pointer // pointer to the circular ring buffer
    elemsize uint16         // size of each element in bytes
    closed   uint32         // 0 = open, 1 = closed
    elemtype *_type          // type descriptor for elements (for
GC)
    sendx    uint           // send index into the ring buffer
    recvx    uint           // receive index into the ring buffer
    recvq    waitq          // linked list of blocked receiver
goroutines
    sendq    waitq          // linked list of blocked sender
goroutines
    lock     mutex          // protects all fields of hchan
}
```

Visual Layout

```
make(chan int, 5) allocates:
hchan (on heap)
............................................................
·  qcount   = 0          (elements currently in buffer)   ·
·  dataqsiz = 5          (buffer capacity)                ·
·  buf ................... .....................          ·
```

```
·                          ·   ·   ·   ·   ·   · (5 slots)·
·                          ....................          ·
·  elemsize = 8          (sizeof(int) on 64-bit)         ·
·  closed   = 0          (channel is open)               ·
·  sendx    = 0          (next write position)           ·
·  recvx    = 0          (next read position)            ·
·  recvq    = {nil, nil} (no waiting receivers)           ·
·  sendq    = {nil, nil} (no waiting senders)             ·
·  lock     = mutex{}    (unlocked)                      ·
............................................................
```

Key Insight: Channel Variables Are Pointers

```
ch := make(chan int, 5)
```

`ch` itself is just a pointer (8 bytes on 64-bit) to the `hchan` on the heap. Passing a channel to a function copies the pointer, not the struct · both the caller and callee operate on the **same** channel. This is why channels work for cross-goroutine communication without additional indirection.

```
goroutine 1                    goroutine 2
..........                    ..........
· ch ............    .......... ch   ·
..........       ·    ·      ..........
                 ·    ·
             ............
             ·  hchan   ·  · same struct
             ............
```

---

2. Buffered vs Unbuffered · What Actually Differs

The **only** structural difference is whether `dataqsiz` is zero.

Unbuffered: `make(chan int)`

```
hchan:
  dataqsiz = 0    · no buffer
  buf      = nil  · no ring buffer allocated
  sendq/recvq     · all synchronization happens here
```

An unbuffered channel has **no storage**. Every send must rendezvous directly with a receiver. This makes unbuffered channels a **synchronization primitive**, not a data structure. The sender blocks until a receiver is ready, and vice versa.

Under the hood, when a send finds a waiting receiver:

- The runtime copies the value **directly from the sender's stack to the receiver's stack**
- No buffer is touched · `runtime.send()` calls `typedmemmove()` directly
- This is the fastest path · one memory copy, no ring buffer overhead

Buffered: `make(chan int, 5)`

```
hchan:
  dataqsiz = 5
```

```
buf ··· [slot0][slot1][slot2][slot3][slot4]   · circular ring buffer
sendx, recvx wrap around using modulo
```

A buffered channel decouples sender and receiver in time. The sender only blocks when the buffer is full; the receiver only blocks when the buffer is empty.

The ring buffer works like this:

```
After: ch <- 10; ch <- 20; ch <- 30
buf: [  10  |  20  |  30  |     |     ]
      ^recvx              ^sendx
After: <-ch  (receives 10)
buf: [      |  20  |  30  |     |     ]
             ^recvx       ^sendx
Indices wrap around with modulo:
  sendx = (sendx + 1) % dataqsiz
  recvx = (recvx + 1) % dataqsiz
```

`make(chan int, 0)` vs `make(chan int)` · Same Thing

Both create an unbuffered channel. `dataqsiz == 0`, no ring buffer.

`make(chan int, 1)` · The Special Case

A buffer of 1 is **not** the same as unbuffered. It allows one send to proceed without a waiting receiver. This is used as a lightweight semaphore:

```
sem := make(chan struct{}, 1)
sem <- struct{}{}   // acquire (doesn't block · buffer has space)
// ... critical section ...
<-sem               // release
```

Many Senders, Many Receivers · How Channels Handle It

A single channel can have **any number of goroutines** sending and receiving simultaneously. Each value goes to exactly **one** receiver · no duplication, no loss.

```
ch := make(chan int, 5)
// 3 receivers competing on the same channel
go func() { fmt.Println("R1 got:", <-ch) }()
go func() { fmt.Println("R2 got:", <-ch) }()
go func() { fmt.Println("R3 got:", <-ch) }()
ch <- 42  // exactly ONE of R1, R2, R3 gets this value
```

Under the hood, when all 3 receivers arrive before any value is sent, they each get parked on `recvq`:

```
hchan.recvq (waiting receivers · FIFO linked list):
..........    ..........    ..........
· sudog  ····· sudog  ····· sudog  ····· nil
· g: R1  ·    · g: R2  ·    · g: R3  ·
..........    ..........    ..........
   first                     last
ch <- 42 arrives:
  1. Lock hchan.lock
  2. Dequeue FIRST sudog (R1) from recvq    · FIFO order
```

```
  3. Copy 42 directly to R1's stack variable
  4. Wake R1 (goready)
  5. Unlock hchan.lock
  6. R2 and R3 remain parked · they wait for the next values
```

The same applies to senders. Multiple senders park on `sendq` in FIFO order:

```
hchan.sendq (waiting senders · FIFO linked list):
..........    ..........
· sudog  ····· sudog  ····· nil
· g: S1  ·    · g: S2  ·
· elem:42·    · elem:99·
..........    ..........
<-ch arrives:
  1. Lock hchan.lock
  2. Dequeue FIRST sudog (S1) from sendq
  3. Copy 42 from S1's stack to receiver's variable
  4. Wake S1 (goready)
  5. Unlock hchan.lock
  6. S2 remains parked · waits until another receiver arrives
```

This is the Worker Pool pattern built into the runtime:

```
                              ··· Worker 1 (receiver) ·· process job
 jobs channel ................ Worker 2 (receiver) ·· process job
                              ··· Worker 3 (receiver) ·· process job
 // All 3 workers call <-jobs · runtime distributes one job to one
worker
 for job := range jobs {
     process(job)
 }
```

Whichever worker finishes first and calls `<-jobs` gets the next job. The `hchan.lock` mutex guarantees no two receivers grab the same value. Zero extra code needed for work distribution.

Summary:

```
.............................................................
·           Many-to-Many Channel Guarantees                 ·
·                                                           ·
·  Senders blocked?   · parked on sendq (FIFO queue)       ·
·  Receivers blocked? · parked on recvq (FIFO queue)       ·
·                                                           ·
·  Value sent     · delivered to exactly ONE receiver       ·
·  Value received · comes from exactly ONE sender           ·
·                                                           ·
·  No duplication. No loss. FIFO ordering within queues.    ·
·  All protected by a single hchan.lock mutex.              ·
.............................................................
```

The `hchan.lock` Mutex · How It Works Under the Hood

Every channel operation (send, receive, close) acquires `hchan.lock` first. This is not a `sync.Mutex` · it's a lower-level **runtime mutex** (`runtime.mutex`) that uses a different strategy than what you get from the `sync` package.

Source: `runtime/lock_futex.go` (Linux) / `runtime/lock_sema.go` (Windows/macOS)

```
// runtime/runtime2.go
type mutex struct {
    lockRankStruct          // for debugging lock ordering
    key uintptr             // 0 = unlocked, other values = locked
state
}
```

The runtime mutex uses a **two-phase locking strategy:**

```
Phase 1: SPIN (optimistic · bet that the lock is released quickly)
.................................................................
  The goroutine tries an atomic compare-and-swap (CAS) on
mutex.key:
    CAS(&key, 0, locked)  ·  if key was 0, set to locked. Done!
  If CAS fails (someone else holds the lock):
    Spin for a few iterations · execute PAUSE instructions
(busy-wait).
    Why? If the lock holder is on another CPU core and will release
    in nanoseconds, spinning is FASTER than sleeping.
    Spin count is limited (~4 iterations on most architectures).
    Spinning only helps for very short critical sections.
Phase 2: SLEEP (pessimistic · lock is contended, stop wasting CPU)
.................................................................
  If spinning didn't acquire the lock:
  On Linux:
    futex(FUTEX_WAIT) · kernel puts the thread to sleep on the mutex
address.
    When the lock holder unlocks: futex(FUTEX_WAKE) wakes ONE
sleeping thread.
    Cost: ~1-2 microseconds (kernel context switch).
  On Windows:
    Uses OS semaphore · similar mechanism, different syscall.
  On macOS:
    Uses pthread_mutex or os_unfair_lock depending on Go version.
```

Why does this matter for channels?

```
.......................................................................
· Every channel send/receive locks hchan.lock:
·
·
·
·   Uncontended (one goroutine using the channel):
·
·     · CAS succeeds immediately · ~5-10ns overhead                  ·
·     · This is the fast path. Channels are cheap when not contested. ·
·
·
·   Low contention (a few goroutines):
·
·     · Short spin · CAS succeeds · ~20-50ns overhead                ·
·     · Still fast. The spin avoids the expensive kernel call.        ·
·
```

```
·
·   High contention (100 goroutines on one channel):
·
·     · Spin fails · futex sleep · kernel wakeup · ~1-2·s overhead   ·
·     · The channel becomes a BOTTLENECK.                             ·
·     · All goroutines serialize through one mutex.                   ·
·     · Solution: shard into multiple channels, or use sync primitives·
····· ····· ····· ····· ····· ····· ····· ····· ····· ····· ····· ····· ·····
```

Comparison: `hchan.lock` **(runtime mutex) vs** `sync.Mutex`**:**

```
····· ····· ····· ····· ····· ····· ····· ····· ····· ····· ····· ····· ·····
·                       · runtime.mutex            · sync.Mutex
   ·
·                       · (used by channels)       · (used by your code)
   ·
····· ····· ····· ····· ····· ····· ····· ····· ····· ····· ····· ····· ·····
· Where used            · Internal runtime only    · User-space Go code
   ·
· Goroutine-aware?      · No · blocks the OS       · Yes · parks the
·
·                       · thread (M), not just     · goroutine (G),
releases  ·
·                       · the goroutine            · the thread (M) for
   ·
·                       ·                          · other goroutines
   ·
· Spin phase            · Yes (limited)            · Yes (adaptive since
   ·
·                       ·                          · Go 1.9, starvation
mode) ·
· Blocking mechanism    · futex / OS semaphore     · runtime.gopark (parks
G, ·
·                       · (puts OS thread to       · M picks another G
from   ·
·                       · sleep)                   · run queue)
   ·
· Why different?        · Runtime can't use its    · Built on top of the
   ·
·                       · own scheduler to park    · runtime scheduler · can
  ·
·                       · goroutines while inside  · cooperatively yield
   ·
·                       · the scheduler code       ·
   ·
····· ····· ····· ····· ····· ····· ····· ····· ····· ····· ····· ····· ·····
```

The critical insight: `hchan.lock` blocks the **OS thread**, not just the goroutine. This is necessary because channel operations are part of the scheduler itself · you can't use the scheduler to sleep while you're inside scheduler code. This is why high-contention channels are expensive: they waste OS threads, not just goroutines.

However, the lock is held for an extremely short time (copy a value, update an index, maybe wake a goroutine). So in practice, contention only matters when you have many goroutines hammering the same channel at extreme throughput (>1M ops/sec).

---

3. Step-by-Step: Send Operation

When you write `ch <- value`, the runtime calls `runtime.chansend()`. There are **three possible paths**, checked in order:

Path 1: Receiver Already Waiting (fastest)

```
ch <- 42   (and there's a goroutine blocked on <-ch)
  1. Lock hchan.lock
  2. Dequeue a waiting receiver from recvq
  3. Copy value DIRECTLY from sender's stack into receiver's
variable
     · runtime.send() · typedmemmove(elem, src, dst)
     · NO ring buffer involvement
  4. Wake the receiver goroutine (change state _Gwaiting ·
_Grunnable)
  5. Unlock hchan.lock
  This is the DIRECT SEND path · fastest because it bypasses the
buffer entirely.

  Sender goroutine G1              Receiver goroutine G2
  .................               .................
  · stack: val=42  · ...........  · stack: v=42    ·
  .................   direct      .................
                      copy           (was parked on
                                      recvq, now
                                      woken up)
```

Path 2: Buffer Has Space

```
ch <- 42   (no waiting receiver, but buffer is not full)
  1. Lock hchan.lock
  2. Copy value into buf[sendx]
     · typedmemmove(elemtype, bufSlot, &value)
  3. sendx = (sendx + 1) % dataqsiz
  4. qcount++
  5. Unlock hchan.lock
  6. Sender continues immediately · no blocking
```

Path 3: Buffer Full (or Unbuffered With No Receiver) · Block

```
ch <- 42   (buffer full or unbuffered, no waiting receiver)
  1. Lock hchan.lock
  2. Create a sudog for this goroutine (see Section 5)
  3. Enqueue sudog onto sendq
  4. Call runtime.gopark() · suspends this goroutine
     · goroutine state: _Grunning · _Gwaiting
     · scheduler picks another goroutine to run
  5. (later, when a receiver arrives, this goroutine is woken)
  6. Unlock hchan.lock
```

Visual Summary

```
ch <- value
·
·· recvq non-empty?
·   ·· YES · DIRECT SEND: copy to receiver's stack, wake receiver
·
·· buffer has space? (qcount < dataqsiz)
·   ·· YES · BUFFER SEND: copy to buf[sendx], advance sendx
·
·· neither?
    ·· PARK: create sudog, enqueue on sendq, goroutine sleeps
```

---

4. Step-by-Step: Receive Operation

When you write `v := <-ch`, the runtime calls `runtime.chanrecv()`. Again, three paths:

Path 1: Sender Already Waiting (unbuffered or full buffer)

Case A · Unbuffered channel with waiting sender:

```
  1. Lock hchan.lock
  2. Dequeue sender from sendq
  3. Copy value DIRECTLY from sender's stack into receiver's
variable
  4. Wake sender goroutine
  5. Unlock hchan.lock
```

Case B · Buffered channel that is full, with waiting sender:

```
  1. Lock hchan.lock
  2. Copy buf[recvx] into receiver's variable (the oldest element)
  3. Copy waiting sender's value into buf[recvx] (fill the slot
just freed)
  4. Advance recvx
  5. Wake sender goroutine
  6. Unlock hchan.lock
  This maintains FIFO order · the receiver gets the oldest buffered
value,
  and the sender's value goes to the end of the buffer.
```

Path 2: Buffer Has Data (no waiting senders)

```
v := <-ch   (buffer has elements, no waiting senders)
  1. Lock hchan.lock
  2. Copy buf[recvx] into receiver's variable
  3. recvx = (recvx + 1) % dataqsiz
  4. qcount--
  5. Unlock hchan.lock
  6. Receiver continues with the value
```

Path 3: Buffer Empty (or Unbuffered With No Sender) · Block

```
v := <-ch   (nothing to receive)
```

```
1. Lock hchan.lock
2. Create a sudog for this goroutine
3. Enqueue sudog onto recvq
4. Call runtime.gopark() · goroutine sleeps
5. (later, when a sender arrives, this goroutine is woken)
6. Value is written directly by the sender (Path 1 of send)
7. Unlock hchan.lock
```

The Two-Value Receive: `v, ok := <-ch`

```
v, ok := <-ch
```

- `ok == true` · value was sent by a sender (normal operation)
- `ok == false` · channel was **closed** and buffer is **empty**; `v` is the zero value

Under the hood, `chanrecv()` returns a `received` boolean. When `closed == 1` and `qcount == 0`, it sets `received = false` and zeroes the receiver's memory.

---

5. The `sudog` · Goroutine Parking

When a goroutine blocks on a channel (send to full, receive from empty), the runtime creates a `sudog` ("sudo-goroutine") · a wrapper that links the goroutine to the channel's wait queue.

Source: `runtime/runtime2.go`

```
type sudog struct {
    g       *g              // the blocked goroutine
    elem    unsafe.Pointer  // pointer to the data being
sent/received
    c       *hchan          // the channel this sudog is parked on
    next    *sudog          // linked list · next waiting goroutine
    prev    *sudog          // linked list · previous waiting
goroutine
    // ... other fields for select, timers
}
```

Wait Queue Structure

```
hchan.sendq (goroutines blocked on send):
..........    ..........    ..........
· sudog  ····· sudog  ····· sudog  ····· nil
· g: G4  ·    · g: G7  ·    · g: G12 ·
· elem:42·    · elem:99·    · elem:7 ·
..........    ..........    ..........
   first         ...          last
hchan.recvq (goroutines blocked on receive):
..........    ..........
· sudog  ····· sudog  ····· nil
· g: G2  ·    · g: G9  ·
· elem:&v·    · elem:&w·      · elem points to the receiver's variable
..........    ..........
```

sudog Lifecycle

```
1. Goroutine G wants to send to full channel
2. Runtime acquires sudog from per-P cache (or allocates new one)
3. Fills in: g = G, elem = &value, c = ch
4. Enqueues onto ch.sendq
5. Calls gopark(G) · G becomes _Gwaiting
6. ... time passes ...
7. Receiver arrives, dequeues this sudog from sendq
8. Copies value from sudog.elem directly
9. Calls goready(G) · G becomes _Grunnable, added to run queue
10. sudog returned to per-P cache for reuse
```

Per-P sudog Cache · Why Channel Ops Are Allocation-Free

To understand the "per-P cache", you first need to know what a **P** is.

The GMP Model (quick recap):

```
.....................................................................
·                        Go Scheduler: GMP Model
·
·
·
·  G = Goroutine    (your code · millions of these)                 ·
·  M = Machine      (OS thread · typically tens of these)            ·
·  P = Processor    (logical CPU · count = GOMAXPROCS, e.g., 8)      ·
·
·
·  Rule: A goroutine (G) can only run when an M has a P.
·
·  Each P has its own LOCAL resources to avoid global locks.
·
·
·
·   P0                P1                P2                P3
·
·   ...........      ...........      ...........      ........... .
·   · run queue·      · run queue·      · run queue·      · run queue· ·
·   · mcache   ·      · mcache   ·      · mcache   ·      · mcache   · ·
·   · sudog    ·      · sudog    ·      · sudog    ·      · sudog    · ·
·   ·  cache   ·      ·  cache   ·      ·  cache   ·      ·  cache   · ·
·   ...........      ...........      ...........      ........... .
·        .                .                .                .        .
·        .                .                .                .        .
·   M0 (thread)      M1 (thread)     M2 (thread)      M3 (thread)  ·
·   running G5       running G12     running G3       running G8    ·
·
·
.....................................................................
```

Each P has its own **sudog free list** · a stack of pre-allocated, reusable sudog structs.

Why "per-P" instead of one global pool?

```
Global pool approach (BAD):
  ............................
  ·  Global sudog free list  ·  · single lock protects this
  ·  ......................  ·
  ·  · s · s · s · s · s ·  ·
  ·  ......................  ·
  ............................
       ·    ·    ·    ·
       ·    ·    ·    ·
      P0   P1   P2   P3      ALL P's compete for ONE lock
                              · contention at high throughput!
Per-P pool approach (GOOD · what Go actually does):
  P0 sudog cache    P1 sudog cache    P2 sudog cache    P3 sudog
cache
  .............    .............    .............    .............
  · s · s · s ·    · s · s · s ·    · s · s · s ·    · s · s · s ·
  .............    .............    .............    .............
       ·                ·                ·                ·
       ·                ·                ·                ·
      P0 only          P1 only          P2 only          P3 only
      NO lock needed!  NO lock needed!  NO lock needed!  NO lock
needed!
```

The key insight: When a goroutine running on P2 needs a sudog (because it's about to block on a channel), it grabs one from P2's local cache ·**no lock, no contention, no heap allocation**. When the sudog is returned (after the goroutine is woken), it goes back to P2's cache for reuse.

This is the same design pattern used throughout the Go runtime:

- **Per-P sudog cache** · for channel blocking (this section)
- **Per-P mcache** · for small memory allocations (avoids global allocator lock)
- **Per-P run queue** · for goroutine scheduling (avoids global queue lock)
- **Per-P defer pool** · for defer struct allocation

The design philosophy: **"If each CPU core has its own resources, cores don't fight over shared locks."**

sudog Cache Lifecycle · Full Picture

```
  ..........................................................................
  ·                    sudog Cache Lifecycle
      .
  ·
      .
  ·  STEP 1: Goroutine G (running on P2) needs to block on channel ch
     .
  ·
      .
  ·    P2's sudog cache: [s1, s2, s3]   · 3 sudogs available
  ·
  ·
      .
  ·    Runtime pops s1 from P2's cache   · NO lock, NO heap allocation
    .
  ·    Fills in: s1.g = G, s1.elem = &value, s1.c = ch
     .
```

```
·    Enqueues s1 onto ch.sendq
   ·
·    Parks G (gopark)
   ·
·
     ·
·    P2's sudog cache: [s2, s3]        · 2 remaining
·
·
     ·
·  STEP 2: A receiver on P0 dequeues s1 from ch.sendq
  ·
·
     ·
·    Copies value from s1.elem
   ·
·    Wakes G (goready) · G goes to a run queue
 ·
·    Returns s1 to... which P's cache?
     ·
·
     ·
·    · The P that is running the wakeup code (P0 in this case)
 ·
·    · s1 goes to P0's cache, NOT P2's!
 ·
·    · This is fine · sudogs are fungible (interchangeable)
·
·
     ·
·  STEP 3: If a P's cache is empty?
   ·
·
     ·
·    · Allocate a new sudog from the heap (mallocgc)
 ·
·    · This is the SLOW path · only happens when the cache is exhausted
·
·    · In practice, sudogs are quickly returned and reused
 ·
·
     ·
·  STEP 4: If a P's cache is too full?
   ·
·
     ·
·    · Excess sudogs are returned to a global pool
 ·
·    · Other P's with empty caches can take from the global pool
 ·
·    · Global pool access DOES require a lock, but rarely happens
 ·
·
     ·
```

```
.....................................................................
```

Why This Matters for Performance

```
Channel send to full buffer (common case):
  1. Need a sudog · grab from P's cache · ~5ns (pointer pop from list)
  2. Park goroutine · ~50ns (scheduler state change)
  3. ... blocked ...
  4. Woken by receiver · ~50ns
  5. Return sudog to P's cache · ~5ns (pointer push to list)
  Total sudog overhead: ~10ns. NO heap allocation. NO GC pressure.
Without per-P cache (hypothetical):
  1. Need a sudog · mallocgc(sizeof(sudog)) · ~200-500ns (heap alloc)
  2. ... same blocking ...
  3. sudog becomes garbage · GC must scan and collect · adds GC
pressure
  Total sudog overhead: ~500ns+ and GC work.
  At 1M channel ops/sec, that's 1M allocations/sec · significant GC
pressure.
```

5b. Visual Guide: Channel Operations End-to-End

The following diagrams show the complete lifecycle of channel operations, combining hchan, ring buffer, sudog, and goroutine state transitions.

Scenario 1: Buffered Channel · Happy Path (No Blocking)

```
ch := make(chan int, 3)      · create channel with buffer of 3
ch <- 10                     · send (buffer has space)
ch <- 20                     · send (buffer has space)
v := <-ch                    · receive (buffer has data)
.............................................................
AFTER make(chan int, 3):
ch ··· hchan {
         qcount: 0          · empty
         dataqsiz: 3        · capacity
         buf: ··· [ _ | _ | _ ]
         sendx: 0   recvx: 0
         sendq: ·   recvq: ·
         closed: 0
       }
.............................................................
AFTER ch <- 10:
hchan {
  qcount: 1                 · one element
  buf: ··· [ 10 | _ | _ ]
            ·recvx  ·sendx=1
  sendq: ·   recvq: ·      · nobody waiting, no sudogs needed
}
G1 (sender) continues immediately · NOT blocked.
.............................................................
```

```
AFTER ch <- 20:
hchan {
  qcount: 2
  buf: ··· [ 10 | 20 | _ ]
             ·recvx     ·sendx=2
  sendq: ·   recvq: ·
}
..............................................................
AFTER v := <-ch:
hchan {
  qcount: 1
  buf: ··· [ _ | 20 | _ ]
                 ·recvx=1  ·sendx=2
  sendq: ·   recvq: ·
}
v = 10 (the oldest value · FIFO order)
G2 (receiver) continues immediately.
```

Scenario 2: Unbuffered Channel · Direct Transfer

```
ch := make(chan int)         · unbuffered (no buffer at all)
..............................................................
GOROUTINE G1: v := <-ch     (receiver arrives first, nobody
sending)
Step 1: G1 checks recvq · sendq is empty, no buffer · must BLOCK
Step 2: Runtime gets sudog from P's cache:
  P2's cache: [s4, s5, s6] · pop s4
  Fill in: s4 = { g: G1, elem: &v, c: ch }
Step 3: Enqueue s4 onto ch.recvq:
hchan {
  dataqsiz: 0          · unbuffered
  buf: nil
  recvq: ··· ··........
             · sudog  ···· nil
             · g: G1  ·
             · elem:&v· · points to v on G1's STACK
             ··........
  sendq: ·
}
Step 4: gopark(G1) · G1 state: _Grunning · _Gwaiting
        G1 is now sleeping. M (OS thread) picks another
goroutine.
..............................................................
LATER · GOROUTINE G2: ch <- 42     (sender arrives)
Step 1: G2 locks hchan.lock
Step 2: G2 checks recvq · found s4 (G1 is waiting!)
Step 3: DIRECT COPY · bypasses buffer entirely:
  G2's stack               G1's stack (frozen · G1 is parked)
  ................         ................
  ·  val = 42    · ......  ·  v = 42      ·
  ................ typedmemmove()  ................
                   (copies 8 bytes directly from stack to stack)
Step 4: Dequeue s4 from recvq. Return s4 to P's cache.
```

```
Step 5: goready(G1) · G1 state: _Gwaiting · _Grunnable
        G1 is placed on a run queue, will resume soon.
Step 6: G2 unlocks hchan.lock. G2 continues immediately.
..............................................................
G1 WAKES UP:
G1 resumes execution at the point after <-ch.
v is already 42 on its stack (written directly by G2).
G1 continues with v = 42. No buffer was involved.
```

Scenario 3: Buffered Channel Full · Sender Blocks, Then Receiver Arrives

```
ch := make(chan int, 2)
ch <- 10   · buffer: [10, _]
ch <- 20   · buffer: [10, 20] · FULL
..............................................................
GOROUTINE G1: ch <- 30     (sender, but buffer is full!)
Step 1: G1 checks · no waiting receivers, buffer FULL · must BLOCK
Step 2: Get sudog from P's cache:
  s1 = { g: G1, elem: &(30), c: ch }
Step 3: Enqueue s1 onto sendq:
hchan {
  qcount: 2 / dataqsiz: 2    · buffer is full
  buf: ··· [ 10 | 20 ]
            ·recvx  ·sendx=0 (wrapped!)
  sendq: ··· ··........
             · sudog  ···· nil
             · g: G1  ·
             · elem:30· · the value G1 wants to send
             ··........
  recvq: ·
}
Step 4: gopark(G1) · G1 sleeps.
..............................................................
GOROUTINE G2: v := <-ch    (receiver arrives!)
This case is special · buffer is full AND a sender is waiting.
The runtime does a clever optimization:
Step 1: G2 takes the OLDEST value from the buffer:
  v = buf[recvx] = buf[0] = 10
Step 2: G1's value (30) fills the slot that was just freed:
  buf[recvx] = 30  (from s1.elem)
Step 3: Advance recvx:
hchan {
  qcount: 2 / dataqsiz: 2    · still full!
  buf: ··· [ 30 | 20 ]       · 30 replaced 10's slot
                ·recvx=1 ·sendx=1
  sendq: ·                     · s1 removed
  recvq: ·
}
Step 4: Wake G1, return sudog to cache.
Result:
  v = 10 (G2 got the OLDEST value · FIFO maintained!)
  G1 unblocked (its value 30 is now in the buffer)
  Buffer is still full: [30, 20] · the receiver took one, sender
```

```
added one
```

Scenario 4: Select with Multiple Channels · Goroutine on Multiple Wait Queues

```
   select {
   case v := <-ch1:     // case 0
   case v := <-ch2:     // case 1
   case ch3 <- 42:      // case 2
   }
   None of the channels are ready. Goroutine G5 must block on ALL
of them.
   ..............................................................
   Step 1: Runtime creates 3 sudogs (from P's cache):
     s1 = { g: G5, c: ch1 }    · for receive on ch1
     s2 = { g: G5, c: ch2 }    · for receive on ch2
     s3 = { g: G5, c: ch3 }    · for send on ch3
   Step 2: Enqueue each on its channel:
   ch1.recvq: [..., s1{g:G5}]    · G5 is waiting to receive from ch1
   ch2.recvq: [..., s2{g:G5}]    · G5 is waiting to receive from ch2
   ch3.sendq: [..., s3{g:G5}]    · G5 is waiting to send to ch3
   Step 3: gopark(G5) · G5 sleeps on ALL three channels
simultaneously.
   ..............................................................
   LATER: Someone sends a value to ch2.
   ch2 processing:
     1. Dequeue s2 from ch2.recvq
     2. Copy value to G5's variable
     3. Wake G5
   G5 wakes up and CLEANS UP the other sudogs:
     4. Remove s1 from ch1.recvq  · G5 is no longer waiting on ch1
     5. Remove s3 from ch3.sendq  · G5 is no longer waiting on ch3
     6. Return s1, s2, s3 to P's cache
   selectgo() returns case index 1 (ch2 was ready).
   ..............................................................
   VISUAL: G5 parked on 3 channels, then woken by ch2:
   BEFORE (G5 sleeping):
   ch1.recvq: ··· ... ··· s1{G5} ···
   ch2.recvq: ··· ... ··· s2{G5} ···   · all three queues have G5
   ch3.sendq: ··· ... ··· s3{G5} ···
           .................
           ·  G5 (_Gwaiting)·   sleeping, waiting for ANY channel
           .................
   AFTER (ch2 delivers value, G5 wakes):
   ch1.recvq: ··· ... ···           · s1 removed (cleanup)
   ch2.recvq: ··· ... ···           · s2 removed (delivered)
   ch3.sendq: ··· ... ···           · s3 removed (cleanup)
           ...................
           ·  G5 (_Grunnable) ·   awake, processing case 1 (ch2)
           ...................
```

Scenario 5: Close Channel with Waiting Receivers

```
   ch := make(chan int, 3)
```

```
ch <- 10
ch <- 20
// 2 goroutines are waiting to receive:
hchan {
  qcount: 2
  buf: ··· [ 10 | 20 | _ ]
  recvq: ··· s1{G3} ··· s2{G7} ··· nil
  closed: 0
}
..............................................................
close(ch):
Step 1: Set closed = 1
Step 2: Wake ALL receivers in recvq:
  G3: receives 10 from buffer (ok=true, buffer had data)
  G7: receives 20 from buffer (ok=true, buffer had data)
Step 3: If there were MORE receivers than buffered values:
  Remaining receivers get (zero value, ok=false)
Step 4: If there were senders in sendq:
  All senders PANIC: "send on closed channel"
..............................................................
AFTER close:
hchan {
  qcount: 0
  buf: ··· [ _ | _ | _ ]       · drained
  recvq: ·                      · all receivers woken
  sendq: ·
  closed: 1                     · permanently closed
}
Any future <-ch returns (0, false) immediately.
Any future ch <- val PANICS.
```

Master Diagram: Complete Channel State Machine

6. Close Semantics · Under the Hood

When you write `close(ch)`, the runtime calls `runtime.closechan()`:

```
close(ch):
  1. Lock hchan.lock
  2. Set ch.closed = 1
  3. Iterate ALL waiting receivers (recvq):
     · For each: set their elem to zero value, wake them
     · They receive (zero value, ok=false)
  4. Iterate ALL waiting senders (sendq):
     · For each: PANIC · "send on closed channel"
     · Actually, these are woken and panic in their goroutine
  5. Unlock hchan.lock
```

The Rules (with runtime explanation)

```
...............................................................................
· Operation on closed channel      · What happens (and WHY)
      ·
...............................................................................
· ch <- value                      · PANIC: "send on closed channel"
      ·
·                                  · Runtime checks ch.closed before
send.    ·
·                                  · Rationale: sending to closed
channel     ·
·                                  · would lose data silently · Go
prefers    ·
·                                  · to crash loud over silent data
loss.     ·
...............................................................................
· v := <-ch  (buffer non-empty)    · Returns buffered value, ok=true
      ·
```

```
·                                   · Closed channels drain remaining
buffer   ·
·                                   · before returning zero values.
      ·
.......................................................................
· v := <-ch  (buffer empty)         · Returns zero value immediately,
ok=false ·
·                                   · Never blocks · closed + empty =
done.    ·
.......................................................................
· close(ch) again                   · PANIC: "close of closed channel"
      ·
·                                   · Runtime checks ch.closed at entry.
      ·
.......................................................................
· close(nil)                        · PANIC: "close of nil channel"
      ·
·                                   · No hchan to set closed on.
      ·
.......................................................................
```

The "Only Sender Closes" Rule

This isn't enforced by the compiler · it's a **convention** backed by the panic semantics:

- If receiver closes, sender panics on next send · program crashes
- If sender closes, receiver just gets zero values · graceful degradation

Multiple senders sharing one channel? Use a `sync.Once` or `sync.WaitGroup` to coordinate a single close after all senders finish. Never have each sender try to close.

```go
// Pattern: multiple senders, one coordinated close
func fanIn(sources ...<-chan int) <-chan int {
    out := make(chan int)
    var wg sync.WaitGroup
    wg.Add(len(sources))
    for _, src := range sources {
        go func(s <-chan int) {
            defer wg.Done()
            for v := range s {
                out <- v
            }
        }(src)
    }
    go func() {
        wg.Wait()    // wait for ALL senders to finish
        close(out)   // single close point
    }()
    return out
}
```

---

7. Select Statement Internals

`select` is the most complex channel operation. It multiplexes across multiple channels.

What the Compiler Generates

```
select {
case v := <-ch1:
    fmt.Println(v)
case ch2 <- 42:
    fmt.Println("sent")
case <-time.After(1 * time.Second):
    fmt.Println("timeout")
default:
    fmt.Println("nothing ready")
}
```

The compiler translates this into a call to `runtime.selectgo()`, passing an array of `scase` structs (one per case):

```
// runtime/select.go
type scase struct {
    c    *hchan         // the channel for this case
    elem unsafe.Pointer // pointer to send/receive data
}
```

The `selectgo()` Algorithm

```
runtime.selectgo(cases []scase, order []uint16):
  Phase 1: RANDOM SHUFFLE
  .......................
  Shuffle the polling order randomly.
  WHY? To prevent starvation. If two cases are always ready,
  both get a fair chance. Without shuffling, the first case
  in source order would always win.
  Phase 2: LOCK ALL CHANNELS
  ..........................
  Lock every unique channel's mutex (in address order to prevent
deadlock).
  This is the expensive part · acquiring N mutexes.
  Phase 3: POLL (non-blocking check)
  ..................................
  Walk cases in shuffled order:
    For each receive case:
      - sendq non-empty? · direct receive from sender · DONE
      - buffer non-empty? · buffer receive · DONE
    For each send case:
      - recvq non-empty? · direct send to receiver · DONE
      - buffer has space? · buffer send · DONE
  If any case is ready · unlock all, return that case.
  If default exists and nothing ready · unlock all, return default.
  Phase 4: ENQUEUE ON ALL CHANNELS (nothing ready, no default)
  ............................................................
  Create a sudog for THIS goroutine for EACH case.
  Enqueue each sudog onto the corresponding channel's sendq or
```

```
recvq.
  The goroutine is now parked on MULTIPLE channels simultaneously.
  Call gopark() · goroutine sleeps.
  Phase 5: WAKEUP
  ..............
  When ANY of the channels becomes ready, the goroutine is woken.
  Dequeue this goroutine's sudogs from ALL OTHER channels.
  Return the case that triggered the wakeup.
```

Visual: Goroutine Parked on Multiple Channels

```
  select {
  case v := <-ch1:     // case 0
  case v := <-ch2:     // case 1
  case ch3 <- 42:      // case 2
  }
  Goroutine G5 is now waiting on 3 channels:
  ch1.recvq: [..., sudog{g:G5, case:0}]
  ch2.recvq: [..., sudog{g:G5, case:1}]
  ch3.sendq: [..., sudog{g:G5, case:2}]
  When ch2 gets a value:
    1. ch2 dequeues sudog{g:G5} from recvq
    2. Copies value to G5's variable
    3. Wakes G5
    4. G5 removes its sudogs from ch1.recvq and ch3.sendq
    5. selectgo returns case index 1
```

Performance: Select is Expensive

```
  Cost of select with N cases:
  · N mutex lock/unlock operations (Phase 2 & unlock)
  · N sudog allocations (if blocking · Phase 4)
  · Random shuffle (O(N) Fisher-Yates)
  · Lock ordering sort (O(N log N) on channel addresses)
  For 2-3 cases: negligible
  For 10+ cases: measurable · consider redesigning
```

Select with Default · Non-Blocking Operation

```
select {
case v := <-ch:
    process(v)
default:
    // ch not ready · do something else
}
```

With `default`, `selectgo` never reaches Phase 4. It polls once and either finds a ready case or falls through to default. This makes it a **non-blocking** channel operation · the Go equivalent of `tryReceive()`.

---

8. Nil Channel Behavior · Why It Blocks Forever

```
var ch chan int   // ch is nil · no hchan exists
<-ch             // blocks forever
ch <- 42         // blocks forever
```

When you operate on a nil channel, `runtime.chansend/chanrecv` check for `c == nil` at the very top:

```
// runtime/chan.go (simplified)
func chansend(c *hchan, ...) bool {
    if c == nil {
        gopark(nil, nil, waitReasonChanSendNilChan, ...)
        // goroutine parked forever · nothing will wake it
        // no hchan exists · no sendq/recvq to enqueue on
        // it's just... gone
    }
    ...
}
```

Why Is This Useful?

Nil channels are a **select control mechanism**. You can dynamically disable select cases by setting their channel to nil:

```
func merge(ch1, ch2 <-chan int) <-chan int {
    out := make(chan int)
    go func() {
        defer close(out)
        for ch1 != nil || ch2 != nil {
            select {
            case v, ok := <-ch1:
                if !ok {
                    ch1 = nil  // disable this case · nil channel
blocks forever
                    continue   // in select, won't be selected
again
                }
                out <- v
            case v, ok := <-ch2:
                if !ok {
                    ch2 = nil  // disable this case
                    continue
                }
                out <- v
            }
        }
    }()
    return out
}
```

Without nil channel semantics, you'd need complex flag logic. Setting `ch1 = nil` makes `select` naturally skip that case forever · the runtime says"nil channel will never be ready" and excludes it from polling.

Why `nil` Instead of `close`? · The Critical Difference

This is a common question: "Why not just close the channel instead of setting it to nil?" Because they have **opposite**

behavior inside a `for-select` loop:

```
  Closed channel in select:
  ..................................................
  ·  <-closedCh  ·  returns (zero, false) INSTANTLY ·
  ·                  select sees it as "ready"      ·
  ·                  picks it over and over and over ·
  ·                  CPU: 100% · (infinite loop)   ·
  ..................................................
  Nil channel in select:
  ..................................................
  ·  <-nilCh     ·  blocks FOREVER                  ·
  ·                  select SKIPS this case entirely ·
  ·                  as if the case doesn't exist    ·
  ·                  CPU: 0% ·                      ·
  ..................................................
```

```
// · WRONG · closing inside for-select creates infinite busy loop:
for {
    select {
    case v, ok := <-ch:
        if !ok {
            // ch is closed, but select will pick this case
            // EVERY iteration · returns (0, false) instantly
            // This becomes an infinite loop burning 100% CPU!
        }
    case v := <-other:
        process(v)    // never gets a chance · closed ch always
"wins"
    }
}
// · CORRECT · setting to nil disables the case:
for ch != nil || other != nil {
    select {
    case v, ok := <-ch:
        if !ok {
            ch = nil       // select ignores this case from now on
            continue
        }
        process(v)
    case v, ok := <-other:
        if !ok {
            other = nil
            continue
        }
        process(v)
    }
}
```

One-line rule:

```
  close(ch)  = "I'm done sending"      · receivers get zero values
FOREVER
  ch = nil   = "pretend this doesn't exist" · select skips it
entirely
```

Nil Channel Summary

```
.................................................................
· Operation         · Nil channel behavior                      ·
.................................................................
· <-ch              · Blocks forever (goroutine parked)          ·
· ch <- value       · Blocks forever (goroutine parked)          ·
· close(ch)         · PANIC: close of nil channel               ·
· len(ch)           · 0                                         ·
· cap(ch)           · 0                                         ·
· select case <-ch  · Case is NEVER selected (effectively skip)  ·
.................................................................
```

---

9. Channel Direction Types

Go channels have three direction types. The compiler enforces these at compile time.

```
chan T      // bidirectional · can send and receive
chan<- T    // send-only · can only send
<-chan T    // receive-only · can only receive
```

Conversions Are One-Way

```
  Bidirectional · send-only:  · implicit conversion
  Bidirectional · recv-only:  · implicit conversion
  Send-only · bidirectional:  · compile error
  Recv-only · bidirectional:  · compile error
  Send-only · recv-only:     · compile error
```

Under the hood, all three are the same `*hchan` pointer. The direction restriction is purely a **compile-time constraint** · zero runtime cost. The runtime doesn't know or care about direction.

Why Direction Matters

Direction communicates **ownership semantics**:

```
// The function PRODUCES values · caller can only READ
func generate(n int) <-chan int {
    ch := make(chan int)  // bidirectional internally
    go func() {
        for i := 0; i < n; i++ { ch <- i }
        close(ch)
    }()
    return ch  // returned as receive-only · caller can't send or
close
}
// The function CONSUMES values · caller sends, function reads
func process(jobs <-chan Job) {
    for job := range jobs {
        // ...
    }
```

```
}
```

This is Go's approach to enforcing **channel ownership at the API boundary**. The sender controls the channel lifecycle (including close). The receiver just reads until closed.

---

10. The `chan struct{}` Pattern · Why Not `chan bool`

You'll see `chan struct{}` throughout Go codebases for signaling:

```
done := make(chan struct{})
close(done)  // signal all listeners
```

Why `struct{}` instead of `bool`?

```
  sizeof(struct{}) = 0 bytes   · zero memory for the value
  sizeof(bool)     = 1 byte    · wastes space for information we
don't use
  The signal is in the OPERATION (send/close), not the VALUE.
  Using bool implies the value matters · "was it true or false?"
  Using struct{} makes intent explicit · "this is a signal, not
data."
```

Under the hood, `runtime.hchan` for `chan struct{}`:

- `elemsize = 0` · no space allocated per buffer slot
- The ring buffer exists but elements take zero bytes
- Send/receive still synchronize goroutines, but copy zero bytes of data

When To Use What

```
chan struct{}    · pure signaling (done, quit, semaphore)
chan bool        · rare, when the true/false value actually matters
chan error       · when you need to communicate success/failure with
detail
chan T           · when you're passing actual data
```

---

11. Production Patterns

Pattern 1: Done / Cancellation (replaced by `context.Context`)

```
// Legacy pattern (pre-context)
done := make(chan struct{})
go worker(done)
// ... later ...
close(done)  // signal worker to stop
// Modern pattern · use context
ctx, cancel := context.WithCancel(context.Background())
go worker(ctx)
// ... later ...
cancel()  // signals ctx.Done() channel
```

Under the hood, `context.WithCancel` creates a `chan struct{}` internally. `ctx.Done()` returns it. `cancel()` calls `close()` on it. Same mechanism, better API.

Pattern 2: Worker Pool with Backpressure

```
func workerPool(numWorkers int, jobs <-chan Job) <-chan Result {
    results := make(chan Result)
    var wg sync.WaitGroup
    for i := 0; i < numWorkers; i++ {
        wg.Add(1)
        go func() {
            defer wg.Done()
            for job := range jobs {    // range blocks until jobs
is closed
                results <- process(job)
            }
        }()
    }
    go func() {
        wg.Wait()
        close(results)
    }()
    return results
}
```

Backpressure: The `jobs` channel buffer size controls how far ahead the producer can get. When the buffer is full, the producer blocks · this is natural backpressure without explicit rate limiting.

Pattern 3: Semaphore (Bounded Concurrency)

```
sem := make(chan struct{}, maxConcurrent)
for _, item := range items {
    sem <- struct{}{}         // acquire · blocks when maxConcurrent
reached
    go func(it Item) {
        defer func() { <-sem }()  // release
        process(it)
    }(item)
}
// Wait for all to finish
for i := 0; i < maxConcurrent; i++ {
    sem <- struct{}{}
}
```

The buffered channel acts as a counting semaphore. Buffer capacity = max concurrent goroutines. This is used in production to limit concurrent DB connections, HTTP requests, or file handles.

Pattern 4: Fan-Out / Fan-In

```
  Fan-Out: one producer, N consumers
       ···· worker 1 ···
  jobs ···· worker 2 ····· merged results
       ···· worker 3 ···
```

```
Fan-In: N producers, one consumer (merge)
```

Fan-out is just multiple goroutines reading from the same channel (the runtime fairly distributes values). Fan-in merges multiple channels into one (see your `Merge` exercise).

Pattern 5: Pipeline

```
// Each stage: goroutine reading from input channel, writing to
output channel
func stage(in <-chan int) <-chan int {
    out := make(chan int)
    go func() {
        defer close(out)
        for v := range in {
            out <- transform(v)
        }
    }()
    return out
}
// Compose: input · stage1 · stage2 · stage3 · output
result := stage3(stage2(stage1(input)))
```

Each stage is a goroutine connected by channels. Cancellation flows backward through the pipeline: when the consumer stops reading, buffered channels fill up, and producers eventually block. For eager cancellation, thread a `context.Context` or `done` channel through each stage.

Pattern 6: Timeout with Context (Production-Grade)

```
// DON'T use time.After in loops (it leaks timers)
// DO use context.WithTimeout
func fetchWithTimeout(ctx context.Context, url string) ([]byte,
error) {
    ctx, cancel := context.WithTimeout(ctx, 5*time.Second)
    defer cancel()  // ALWAYS cancel to release resources
    req, _ := http.NewRequestWithContext(ctx, "GET", url, nil)
    resp, err := http.DefaultClient.Do(req)
    // ...
}
```

Why not `time.After`? In a loop, each `time.After` creates a timer that lives until it fires · even if the select case was not chosen. This leaks timers. `context.WithTimeout` + `defer cancel()` cleans up immediately.

Pattern 7: Or-Done Channel (Elegant Cancellation)

```
// orDone wraps a channel read to respect cancellation
func orDone(ctx context.Context, in <-chan int) <-chan int {
    out := make(chan int)
    go func() {
        defer close(out)
        for {
            select {
            case <-ctx.Done():
                return
            case v, ok := <-in:
```

```
                if !ok { return }
                select {
                case out <- v:
                case <-ctx.Done():
                    return
                }
            }
        }
    }()
    return out
}
```

This pattern wraps any channel to make it cancellation-aware. Without it, a goroutine blocked on `<-in` won't notice cancellation until the next value arrives.

---

12. Performance Characteristics & When NOT to Use Channels

Cost of Channel Operations

```
.......................................................................
· Operation                       · Approx Cost   · Why
        ·
.......................................................................
· Unbuffered send+recv (paired)   · ~200-300ns    · Mutex lock +
gopark/goready + ·
·                                 ·               · context switch
        ·
.......................................................................
· Buffered send (not full)        · ~50-100ns     · Mutex lock + memcopy
        ·
.......................................................................
· Buffered recv (not empty)       · ~50-100ns     · Mutex lock + memcopy
        ·
.......................................................................
· Select with 2 cases             · ~300-500ns    · 2 mutex locks + poll
+ sudog  ·
.......................................................................
· Select with N cases             · ~N × 150ns    · N mutex locks +
shuffle +     ·
·                                 ·               · sort + poll
        ·
.......................................................................
· atomic.AddInt64                 · ~5-15ns       · Single CPU
instruction (LOCK  ·
·                                 ·               · XADD)
        ·
.......................................................................
· sync.Mutex Lock+Unlock          · ~20-30ns      · Atomic CAS + possible
OS wait ·
· (uncontended)                   ·               ·
        ·
.......................................................................
```

When NOT to Use Channels

"Channels orchestrate; mutexes serialize." Use the right tool:

```
DON'T use channels for:
.......................
  · Simple counter/accumulator       · use sync/atomic
  · Protecting shared data structure · use sync.Mutex or sync.RWMutex
  · One-time initialization          · use sync.Once
  · Object pooling                   · use sync.Pool
  · Read-heavy shared config         · use atomic.Value or sync.RWMutex
DO use channels for:
....................
  · Goroutine-to-goroutine communication (passing data/ownership)
  · Signaling events (done, quit, ready)
  · Coordinating pipeline stages
  · Fan-out / fan-in patterns
  · Rate limiting / semaphore
  · Streaming results from producer to consumer
```

The Contention Problem

A single channel used by 100 goroutines means 100 goroutines competing for **one mutex** (`hchan.lock`). This serializes what should be concurrent work.

Solutions:

- **Shard channels**: instead of one channel, use N channels and hash-assign goroutines
- **Batch sends**: accumulate values locally, send a slice periodically
- **Use sync primitives**: for simple shared state, mutexes are faster

---

13. Common Bugs & Gotchas

Bug 1: Goroutine Leak · Forgetting to Close

```
// BUG: if the caller stops reading, the goroutine blocks forever
on send
func generate() <-chan int {
    ch := make(chan int)
    go func() {
        for i := 0; ; i++ {
            ch <- i  // blocks forever if nobody reads
        }
    }()
    return ch
}
// FIX: accept a done/context for cancellation
func generate(ctx context.Context) <-chan int {
    ch := make(chan int)
    go func() {
        defer close(ch)
```

```
        for i := 0; ; i++ {
            select {
            case ch <- i:
            case <-ctx.Done():
                return
            }
        }
    }()
    return ch
}
```

Bug 2: Send on Closed Channel · Panic

```
// BUG: race between close and send
close(ch)
ch <- 42  // PANIC
// This happens in fan-out when multiple goroutines share a channel
// and one closes it while others are still sending.
// FIX: coordinate with WaitGroup (see Section 6)
```

Bug 3: Range Over Unclosed Channel · Deadlock

```
ch := make(chan int)
go func() {
    ch <- 1
    ch <- 2
    // forgot close(ch)!
}()
for v := range ch {  // blocks forever after receiving 2 · waiting
for close
    fmt.Println(v)
}
// DEADLOCK: "all goroutines are asleep"
```

Bug 4: time.After in a Loop · Timer Leak

```
// BUG: each iteration creates a new timer that won't be GC'd until
it fires
for {
    select {
    case v := <-ch:
        process(v)
    case <-time.After(5 * time.Second):  // NEW timer every
iteration!
        return
    }
}
// FIX: reuse a timer
timer := time.NewTimer(5 * time.Second)
defer timer.Stop()
for {
    select {
```

```
    case v := <-ch:
        process(v)
        if !timer.Stop() {
            <-timer.C
        }
        timer.Reset(5 * time.Second)
    case <-timer.C:
        return
    }
}
```

Bug 5: Sending Large Structs Through Channels · Hidden Copies

```
type BigStruct struct {
    Data [1024]byte
    // ... many fields
}
ch := make(chan BigStruct)  // each send copies 1024+ bytes into
the buffer!
ch <- bigValue              // memcopy into hchan.buf
// FIX: send a pointer (8 bytes copied instead of 1024)
ch := make(chan *BigStruct)
ch <- &bigValue
// BUT: now you share mutable state · the sender must not modify
after sending
```

---

14. Quick Reference Card

```
HCHAN STRUCTURE
...............
runtime.hchan { buf, qcount, dataqsiz, sendx, recvx, sendq, recvq,
lock, closed }
  ·· Channel variable is a pointer to hchan (8 bytes)
  ·· buf is a circular ring buffer (nil for unbuffered)
  ·· sendq/recvq are doubly-linked lists of sudog (parked goroutines)
  ·· Every operation acquires hchan.lock (runtime mutex)
MANY-TO-MANY
.............
  Multiple senders OK · parked on sendq in FIFO order
  Multiple receivers OK · parked on recvq in FIFO order
  Each value · exactly ONE receiver. No duplication, no loss.
  Worker pool = multiple goroutines ranging over same channel
HCHAN.LOCK (runtime mutex internals)
....................................
  Phase 1: Spin · atomic CAS on mutex.key (~5-10ns if uncontended)
  Phase 2: Sleep · futex/semaphore (OS puts thread to sleep, ~1-2·s)
  Key: blocks the OS THREAD, not just the goroutine
  Why: channel code IS scheduler code, can't use scheduler to park
  Impact: high contention (100 goroutines, 1 channel) wastes OS
threads
SEND PATHS (ch <- value)
```

```
.......................
  1. Receiver waiting?   · direct copy to receiver's stack (fastest)
  2. Buffer has space?   · copy to buf[sendx]
  3. Neither?            · park goroutine on sendq
RECEIVE PATHS (v := <-ch)
.......................
  1. Sender waiting?     · direct copy from sender's stack
  2. Buffer has data?    · copy from buf[recvx]
  3. Neither?            · park goroutine on recvq
CLOSE SEMANTICS
...............
  close(ch)             · sets closed=1, wakes all waiters
  send to closed        · PANIC
  recv from closed      · returns buffered values, then zero values
(ok=false)
  close nil             · PANIC
  close closed          · PANIC
NIL CHANNEL
...........
  send to nil           · blocks forever (goroutine parked
permanently)
  recv from nil         · blocks forever
  close nil             · PANIC
  select case on nil    · case is never selected (use for dynamic
disable)
SELECT INTERNALS
................
  1. Shuffle case order randomly (fairness)
  2. Lock all channels (address order to prevent deadlock)
  3. Poll each case (non-blocking check)
  4. If nothing ready & no default · park on all channels
  5. First channel ready · wake, dequeue from others, return case
DIRECTION TYPES (compile-time only, zero runtime cost)
......................................................
  chan T       bidirectional
  chan<- T     send-only (producer side)
  <-chan T     receive-only (consumer side)
PERFORMANCE RULES
.................
  Channels orchestrate, mutexes serialize
  Buffered send/recv: ~50-100ns (mutex + memcopy)
  Unbuffered pair:    ~200-300ns (mutex + context switch)
  Select with N:      ~N × 150ns (N mutexes + shuffle)
  Use atomic for counters, mutex for shared state, channels for
communication
TOOLS
.....
  GODEBUG=schedtrace=1000    # goroutine scheduler trace
  go tool trace              # visual timeline of goroutines,
channels, GC
  go test -race ./...        # data race detection · NON-NEGOTIABLE
  runtime.NumGoroutine()     # detect goroutine leaks in tests
```

One-Line Summary

> A channel is a pointer to `runtime.hchan` · a mutex-protected struct with a circular ring buffer and two wait queues (sendq/recvq). Sends and receives follow three paths (direct transfer · buffer · park), select multiplexes by parking on all channels simultaneously, and nil channels block forever · a feature, not a bug, for dynamic select control.

---

15. Select in Practice · Patterns, Execution Model & Production Scenarios

Select Executes ONCE · It Is NOT a Loop

This is the most common misconception. A `select` statement is like a `switch` · it evaluates once, picks one case, executes it, and is done. **There is no implicit looping.**

```
select {
case v := <-ch1:
    fmt.Println("got from ch1:", v)
case v := <-ch2:
    fmt.Println("got from ch2:", v)
default:
    fmt.Println("nothing ready")
}
fmt.Println("select is DONE · execution continues here")
```

```
  Execution flow:

  ......................................
  ·            select { ... }          ·
  ·                                    ·
  ·  Are any cases ready?              ·
  ·  ··· YES · pick one (random if many) ·
  ·  ·         execute its body        ·
  ·  ·         EXIT select             ·
  ·  ··· NO  · is there a default?     ·
  ·       ··· YES · execute default body ·
  ·       ·         EXIT select        ·
  ·       ··· NO  · BLOCK (gopark)     ·
  ·                 wait until a case   ·
  ·                 becomes ready       ·
  ·                 execute its body    ·
  ·                 EXIT select        ·
  ......................................
  ·
  ·
  Next line of code runs here
```

The `for-select` Loop · YOU Add the Loop

When you want continuous listening, you wrap `select` in a `for` loop yourself:

```
for {
    select {
```

```
    case v := <-ch:
        process(v)
    case <-ctx.Done():
        return   // breaks out of BOTH select and for
    }
}
```

Critical distinction:

```
  select { ... }              · runs ONCE, like switch
  for { select { ... } }     · runs FOREVER, you must break/return to
stop
  for v := range ch { ... }  · runs until channel is closed (simpler
for single channel)
```

When to use which:

```
  ..............................................................................
  · Pattern                          · When to Use
          ·
  ..............................................................................
  · v := <-ch                        · Single blocking receive, you know
data      ·
  ·                                  · will come, no cancellation needed
           ·
  ..............................................................................
  · for v := range ch                · Drain a single channel until it
closes      ·
  ·                                  · (simplest consumer pattern)
           ·
  ..............................................................................
  · select { cases... }              · ONE-TIME check across multiple
channels     ·
  · (no loop)                        · or non-blocking
tryReceive/trySend          ·
  ..............................................................................
  · for { select { cases... } }      · Continuous listening on multiple
channels   ·
  ·                                  · with cancellation · the EVENT LOOP
pattern  ·
  ..............................................................................
```

Random Selection · Why and How

When multiple cases are ready simultaneously, `select` picks one **uniformly at random**:

```
ch1 := make(chan string, 1)
ch2 := make(chan string, 1)
ch1 <- "from ch1"
ch2 <- "from ch2"
// Both cases are ready · which one runs?
select {
case v := <-ch1:
    fmt.Println(v)    // ~50% of the time
case v := <-ch2:
```

```
    fmt.Println(v)    // ~50% of the time
}
```

Under the hood (from `selectgo` in `runtime/select.go`):

```
  Phase 1: SHUFFLE · Fisher-Yates shuffle on case order

  Cases in source order:  [ch1, ch2]
  After shuffle:          [ch2, ch1]   · random permutation

  Phase 3: POLL · walk cases in SHUFFLED order

  First shuffled case (ch2) · ready? YES · execute it, done.

  Next run, shuffle might produce [ch1, ch2]:
  First shuffled case (ch1) · ready? YES · execute it, done.
```

Why random, not first-case-wins?

```
  If select always chose the first ready case:

  for {
      select {
      case v := <-highPriority:     // always checked first
          process(v)
      case v := <-lowPriority:      // STARVED if highPriority is
always busy
          process(v)
      }
  }

  With a busy highPriority channel, lowPriority would NEVER be
selected.
  Random selection guarantees fairness · both channels get served.
```

What if you WANT priority? Use nested selects:

```
for {
    // Try high priority first (non-blocking)
    select {
    case v := <-highPriority:
        process(v)
        continue       // go back to top, check high priority again
    default:
    }

    // Nothing high-priority · wait for anything
    select {
    case v := <-highPriority:
        process(v)
    case v := <-lowPriority:
        process(v)
    case <-ctx.Done():
        return
    }
```

```
}
```

The `default` Case · Behavior and Dangers

`default` turns `select` from a blocking operation into a **non-blocking poll**:

```
WITHOUT default:                    WITH default:
.................                   .................
select {                            select {
case v := <-ch:                     case v := <-ch:
    process(v)                          process(v)
}                                   default:
// goroutine SLEEPS here                // runs immediately
// until ch has data                }
// (gopark · wait queue)            // goroutine NEVER sleeps
                                    // checks once, moves on
```

The `for-select-default` danger · busy spin:

```
// · CPU KILLER · this burns 100% CPU on one core
for {
    select {
    case v := <-ch:
        process(v)
    default:
        // nothing ready · loop immediately checks again
        // millions of iterations per second, all doing nothing
    }
}
// · FIX 1: Remove default · let select block
for {
    select {
    case v := <-ch:
        process(v)
    case <-ctx.Done():
        return
    }
    // goroutine sleeps until ch or ctx.Done() is ready · zero CPU
}
// · FIX 2: If you need default, add a sleep or yield
for {
    select {
    case v := <-ch:
        process(v)
    default:
        time.Sleep(10 * time.Millisecond)   // back off, don't spin
    }
}
// · FIX 3: Use default only for ONE-TIME checks, not in loops
select {
case v := <-ch:
    process(v)
default:
    fallback()     // runs once, no loop
```

```
}
```

Production Scenario 1: HTTP Handler · Try Cache, Fall Back to DB

```
func getUser(w http.ResponseWriter, r *http.Request) {
    userID := r.PathValue("id")

    // Try the cache channel (non-blocking):
    select {
    case cached := <-cacheResults:
        if cached.ID == userID {
            json.NewEncoder(w).Encode(cached)
            return
        }
    default:
        // cache miss · fall through to DB
    }

    // Blocking wait with request deadline:
    resultCh := make(chan User, 1)
    go func() { resultCh <- queryDB(userID) }()

    select {
    case user := <-resultCh:
        json.NewEncoder(w).Encode(user)
    case <-r.Context().Done():
        // client disconnected or request timeout
        http.Error(w, "timeout", http.StatusGatewayTimeout)
    }
}
```

```
  Flow:
  ............................................................
  ·  Request arrives                                         ·
  ·  ··· select + default: check cache (non-blocking)        ·
  ·  ·   ··· HIT  · respond immediately, done                ·
  ·  ·   ··· MISS · fall through                             ·
  ·  ·                                                       ·
  ·  ··· select + ctx.Done(): wait for DB (bounded)          ·
  ·      ··· DB responds   · respond with data, done         ·
  ·      ··· ctx cancelled · respond 504, done               ·
  ·                                                          ·
  ·  No goroutine leak: either DB finishes or context cancels ·
  ............................................................
```

Production Scenario 2: Worker Event Loop

```
func worker(ctx context.Context, jobs <-chan Job, ticker
*time.Ticker) {
    for {
        select {
        case job := <-jobs:
            // Process incoming work
```

```
            process(job)

        case <-ticker.C:
            // Periodic maintenance (flush buffers, report metrics)
            flushBuffers()
            reportMetrics()

        case <-ctx.Done():
            // Graceful shutdown · drain remaining jobs
            for {
                select {
                case job := <-jobs:
                    process(job)     // finish in-flight work
                default:
                    return           // no more jobs, exit cleanly
                }
            }
        }
    }
}
```

```
This is the classic "event loop" in Go:

............ for-select loop ............
·                                       ·
·  JOBS ····· process(job)              ·  · primary work
·                                       ·
·  TICKER ····· flush + metrics         ·  · periodic maintenance
·                                       ·
·  CTX.DONE ··· drain remaining · exit  ·  · graceful shutdown
·                                       ·
·  The goroutine SLEEPS between events. ·
·  Zero CPU when idle. Wakes instantly  ·
·  when any channel has data.           ·
.........................................

Note the drain loop on shutdown: it uses select+default
(non-blocking) to process remaining jobs without blocking
forever on an empty channel.
```

Production Scenario 3: Rate Limiter (tryAcquire)

```
type RateLimiter struct {
    tokens chan struct{}
}
func NewRateLimiter(rate int) *RateLimiter {
    rl := &RateLimiter{tokens: make(chan struct{}, rate)}
    // Fill with initial tokens
    for i := 0; i < rate; i++ {
        rl.tokens <- struct{}{}
    }
    // Refill tokens periodically
    go func() {
```

```
        ticker := time.NewTicker(time.Second / time.Duration(rate))
        defer ticker.Stop()
        for range ticker.C {
            select {
            case rl.tokens <- struct{}{}:
                // token added
            default:
                // bucket full, discard · this is tryAcquire in
reverse (trySend)
            }
        }
    }()
    return rl
}
// TryAcquire · non-blocking check: is a token available?
func (rl *RateLimiter) TryAcquire() bool {
    select {
    case <-rl.tokens:
        return true    // got a token · proceed
    default:
        return false   // no tokens · reject request
    }
}
// Acquire · blocking wait: wait until a token is available (with
deadline)
func (rl *RateLimiter) Acquire(ctx context.Context) error {
    select {
    case <-rl.tokens:
        return nil     // got a token
    case <-ctx.Done():
        return ctx.Err()   // deadline exceeded or cancelled
    }
}

  TryAcquire (select+default):
    "Is a token available RIGHT NOW? Yes · take it. No · reject."
    Used for: immediate reject (HTTP 429 Too Many Requests)

  Acquire (select+ctx.Done):
    "Wait for a token, but respect my deadline."
    Used for: queue the request, serve when capacity is available
```

Production Scenario 4: Heartbeat / Health Monitor

```
func monitorService(ctx context.Context, healthCh <-chan struct{})
{
    timeout := 5 * time.Second
    timer := time.NewTimer(timeout)
    defer timer.Stop()

    for {
        select {
        case <-healthCh:
```

```
            // Got heartbeat · service is alive, reset timer
            if !timer.Stop() {
                <-timer.C     // drain the channel if timer already
fired
            }
            timer.Reset(timeout)

        case <-timer.C:
            // No heartbeat for 5 seconds · service is dead
            alertOps("service unresponsive")
            timer.Reset(timeout)

        case <-ctx.Done():
            return
        }
    }
}

  Timeline:
  ··heartbeat····heartbeat···............heartbeat··........
       .              .            .           .
       .              .            .           .
     reset          reset       TIMEOUT!     reset
     timer          timer       alert ops    timer
  Three channels, one goroutine · the for-select event loop handles
  all three concerns cleanly.
```

Production Scenario 5: First Response Wins (Fan-Out to Multiple Backends)

```
func queryFastest(ctx context.Context, query string, backends
[]Backend) (Result, error) {
    ctx, cancel := context.WithCancel(ctx)
    defer cancel()   // cancel all other backends when one responds

    resultCh := make(chan Result, len(backends))   // buffered · no
goroutine leak

    for _, b := range backends {
        go func(backend Backend) {
            if r, err := backend.Query(ctx, query); err == nil {
                select {
                case resultCh <- r:
                default:
                    // another result already sent · discard this one
                }
            }
        }(b)
    }

    select {
    case r := <-resultCh:
        return r, nil          // first response wins
    case <-ctx.Done():
```

```
        return Result{}, ctx.Err()
    }
}

  ..............
  · Backend A  ···· 50ms  ··· resultCh ··· WINNER (first in)
  ..............
  · Backend B  ···· 120ms ··· select+default · discarded (already have
result)
  ..............
  · Backend C  ···· ctx cancelled (cancel() called after A responded)
  ..............

  Key details:
  - Buffered channel (len(backends)) prevents goroutine leak
    if multiple backends respond before the select reads
  - select+default inside goroutines prevents blocking on send
    when result channel already has a value
  - defer cancel() cleans up slow backends via context
```

Select Execution Model · Complete Mental Model

```
  ......................................................................
  ·                      SELECT EXECUTION SUMMARY
  ·
  ·
  ·
  ·  1. select runs ONCE per encounter (like switch, not like for)
  ·
  ·  2. If multiple cases ready · pick one at RANDOM (fairness)
·
  ·  3. If no cases ready + default · execute default, exit
·
  ·  4. If no cases ready + no default · BLOCK (gopark on all channels)
·
  ·  5. When blocked, first channel that becomes ready · wake + execute
·
  ·
  ·
  ·  default makes it non-blocking:
  ·
  ·    select + default = tryReceive/trySend (check once, don't wait)
  ·
  ·    select - default = blocking wait (sleep until something
happens) ·
  ·
  ·
  ·  for-select = event loop (continuous listening):
  ·
  ·    for { select { ... } }  = keep checking, handle events forever
 ·
  ·    for + select + default  = BUSY SPIN (danger! burns CPU)
  ·
```

```
  ·    for + select - default  = EFFICIENT event loop (sleeps when
idle)·

---

1. Stack vs Heap · The Fundamental Decision

Every value lives in one of two places. The compiler chooses at compile time.

Stack · Per-Goroutine, Ultra-Fast

Each goroutine owns a private stack. Allocation is just adjusting the stack pointer (SP) · a single CPU instruction. Deallocation is free: function return restores SP.

```
G1 Stack (2KB-1MB)            G2 Stack (independent)
....................          ....................
·   main() frame   ·          ·  handler() frame ·
·  ..............  ·          ·  ..............  ·
·  · local vars ·  ·          ·  · local vars ·  ·
·  ..............  ·          ·  ..............  ·
....................          ....................
·  doWork() frame  ·          ·  query() frame   ·
·  ..............  ·          ·  ..............  ·
·  · x := 42    ·  ·          ·  · buf [64]B  ·  ·
·  · y := 3.14  ·  ·          ·  · n := 0     ·  ·
·  ..............  ·          ·  ..............  ·
....................          ....................
·  · SP (grows     ·          ·  · SP            ·
·    downward)     ·          ·                  ·
```

```
  ....................          ....................
```

Heap · Shared, GC-Managed

The heap is shared across all goroutines. The GC scans and reclaims it.

```
                    ........................... HEAP ........................
                    .  .............  .............  .............      .
      G1 ............  · User{     ·  · []byte    ·  · *Config{} ...... G3
                    .  ·  Name:"A" ·  · len=1024  ·  ·           ·      ·
      G2 ............  · }         ·  ·           ·  .............      .
                    .  .............  .............                      .
                    ·  Managed by GC · concurrent mark and sweep
.
                    ......................................................
```

The Cost Gap

```
.......................................................................
· Property          · Stack             · Heap                        ·
.......................................................................
· Allocation cost   · ~1ns (SP adjust)  · ~25-50ns (runtime.mallocgc)  ·
· Deallocation      · Free (SP restore) · GC background cost           ·
· Synchronization   · None (private)    · GC coordination              ·
· Access speed      · Hot in L1 cache   · Pointer chase, cache miss    ·
· Who decides?      · Compiler (escape  · Compiler (escape analysis)   ·
·                   · analysis)         ·                              ·
.......................................................................
```

Source: `runtime/stack.go` · goroutine stack management. Stacks start at 2-8KB, grow by copying to a 2x buffer (detected at function preamble), shrink during GC if <25% used.

---

2. Escape Analysis · How the Compiler Decides

Escape analysis answers: "Can this value live on the stack, or must it escape to heap?"

Source: `cmd/compile/internal/escape/`

```
go build -gcflags='-m' ./...        # what escapes
go build -gcflags='-m -m' ./...     # WHY it escapes
```

Rule 1 · Pointer Outlives Function · Escapes

```
func newUser(name string) *User {
    u := User{Name: name}       // · escapes to heap
    return &u                   // pointer survives function return
}
// gcflags: "moved to heap: u"
func processUser(name string) string {
    u := User{Name: name}      // · stays on stack
    return u.Name              // value copied, no pointer escape
}
```

Rule 2 · Assigned to Interface · Usually Escapes

```
func greet(u User) {
    fmt.Println(u)              // · u escapes to heap
}
// Println(a ...any) · u boxed into eface{_type,
data=unsafe.Pointer(&u)}
// Compiler can't prove Println won't store the pointer
```

Rule 3 · Sent to Channel · Escapes

```
func produce(ch chan *Data) {
    d := Data{Value: 42}       // · escapes to heap
    ch <- &d                   // receiving goroutine may outlive
sender
}
```

Rule 4 · Closure Captures Escaping Variable · Escapes

```
func makeCounter() func() int {
    count := 0                 // · escapes to heap
    return func() int {        // closure outlives makeCounter
        count++
        return count
    }
}
```

Rule 5 · Too Large for Stack · Escapes

```
func bigAlloc() {
    buf := make([]byte, 1<<20)  // 1MB · escapes to heap
    _ = buf
}
```

Common Surprise Escapes

```
.......................................................................
· Code                            · Why It Escapes
 ·
.......................................................................
· fmt.Println(x)                  · x boxed into interface{} arg
 ·
· fmt.Sprintf("%d", n)            · n boxed, result string allocated
 ·
· return &localVar                · pointer outlives stack frame
  ·
· go func() { use(x) }()         · closure captures x, goroutine
escapes·
· someSlice = append(s, v)        · growth may allocate new backing
array·
· errors.New("msg")               · returns *errorString on heap
 ·
```

```
     ......................................................................
```

---

3. The Memory Allocator · TCMalloc-Inspired

Source: `runtime/malloc.go`, `runtime/mcache.go`, `runtime/mcentral.go`, `runtime/mheap.go`

Three Size Classes

```
       Tiny (<16B, no ptrs)    Small (16B-32KB)        Large (>32KB)
       ....................    ..................      ..............
       Packed into 16-byte     ~67 size classes         Direct from
     mheap
       blocks. Multiple        (8,16,32,48,64...       Rounded to page
       small objects share     up to 32KB)              multiple (8KB
     pages)
       one allocation.
```

The Three-Tier Allocation Path

```
       runtime.mallocgc(size, typ, needzero)
       .
       ·  size > 32KB?
       ·  ·· YES ................................... mheap (global, locked) · OS
       ·  ·· NO
       ·      ·
       ·      ·
       ......................................................................
       · TIER 1: mcache (per-P, NO LOCK)
      .
       ·  Each P has a private mcache with one mspan per size class.
      .
       ·  mcache.alloc[sizeclass] · mspan has free slot? · return. (~25ns)  ·
       ......................................................................
                 · span full
                 .
       ......................................................................
       · TIER 2: mcentral (per-size-class, LOCKED)
      .
       ·  Global pool of partial/full spans per size class.
      .
       ·  cacheSpan() · find partial span · move to mcache. (~100ns)        ·
       ......................................................................
                 · no spans available
                 .
       ......................................................................
       · TIER 3: mheap (global, LOCKED)
      .
       ·  Allocates new spans from free pages or requests from OS.
      .
       ·  mheap.alloc(npages) · carve span. (~500ns, or ·s if OS call)     ·
       ......................................................................
```

Spans · The Unit of Memory Management

An `mspan` (`runtime/mheap.go`) is a contiguous run of 8KB pages divided into fixed-size slots of a given size class.

```
  mspan (size class = 32 bytes, 256 objects per span)
  ....................................................
  · obj0 · obj1 · obj2 · obj3 · obj4 · obj5 · ...     ·
  · 32B  · 32B  · 32B  · 32B  · 32B  · 32B  ·         ·
  · used · FREE · used · FREE · used · FREE ·         ·
  ....................................................
  allocBits:  1  0  1  0  1  0  ...   (tracks which slots are in
use)
  gcmarkBits: 1  0  1  0  0  0  ...   (tracks which are marked
alive)
```

---

4. The Garbage Collector · Tri-Color Mark and Sweep

Concurrent, non-generational, non-compacting. Objects don't move once allocated.

Source: `runtime/mgc.go`, `runtime/mgcmark.go`, `runtime/mgcsweep.go`

The Tri-Color Abstraction

```
  WHITE · not yet seen. If still white after marking · GARBAGE.
  GREY  · seen, but children (pointers) NOT yet scanned.
  BLACK · fully scanned. All children are grey or black. ALIVE.
```

Step-by-Step: A GC Cycle

```
  STEP 1 · Mark Roots (STW pause #1, <200·s)
  ..........................................
  Stop all goroutines. Enable write barrier.
  Mark root-reachable objects GREY.
  Stacks:        Heap objects:
  .......       .....  .....  .....  .....  .....
  ·  ............ A ·  · B ·  · C ·  · D ·  · E ·
  ·  .......    ·GRY·  ·WHT·  ·WHT·  ·WHT·  ·WHT·
  .......  ·    .....  .....  .....  .....  .....
           ·      · points to B
           ·      ·
           ·    .....
           ...... F ·   A.ref·B,  B.ref·C, B.ref·D
                ·GRY·   E has no references (garbage)
                .....

  STEP 2 · Concurrent Mark (goroutines resume)
  ............................................
  GC goroutines scan grey objects alongside application.
  Scan A (grey·black): A·B · mark B grey
  .....  .....  .....  .....  .....  .....
```

```
· A ···· B ·   · C ·   · D ·   · E ·   · F ·
·BLK·   ·GRY·   ·WHT·   ·WHT·   ·WHT·   ·GRY·
·····   ·····   ·····   ·····   ·····   ·····
Scan B (grey·black): B·C, B·D · mark C,D grey
·····   ·····   ·····   ·····   ·····   ·····
· A ···· B ···· C ·   · D ·   · E ·   · F ·
·BLK·   ·BLK·   ·GRY·   ·GRY·   ·WHT·   ·GRY·
·····   ·····   ·····   ·····   ·····   ·····
Scan C, D, F (grey·black): no new children
·····   ·····   ·····   ·····   ·····   ·····
· A ·   · B ·   · C ·   · D ·   · E ·   · F ·
·BLK·   ·BLK·   ·BLK·   ·BLK·   ·WHT·   ·BLK·
·····   ·····   ·····   ·····   ·····   ·····
No more grey · marking complete.

STEP 3 · Mark Termination (STW pause #2, <200·s)
...............................................
Stop goroutines. Disable write barrier. Finalize marking.
STEP 4 · Concurrent Sweep (goroutines resume)
.............................................
Reclaim WHITE objects. E is freed.
·····   ·····   ·····   ·····   ·····   ·····
· A ·   · B ·   · C ·   · D ·   · E ·   · F ·
· · ·   · · ·   · · ·   · · ·   · · ·   · · ·
·live·   ·live·   ·live·   ·live·   ·FREE·   ·live·
·····   ·····   ·····   ·····   ·····   ·····
```

The Tri-Color Invariant

Black never points directly to white · enforced by the write barrier:

```
· ALLOWED:                · VIOLATED:
BLACK ··· GREY             BLACK ··· WHITE
BLACK ··· BLACK            (write barrier prevents this)
GREY  ··· WHITE/GREY/BLACK
```

---

5. Write Barrier · Protecting Concurrent Marking

Source: `runtime/mbarrier.go`

The Problem Without It

```
Time 0: GC scans A (·black). A.ref·B, so B marked grey.
Time 1: App runs: A.ref = C; B.ref = nil  (moved pointer to C)
Time 2: GC scans B (·black): no children.
·····       ·····       ·····
· A ·------· C ·       · B ·
·BLK·       ·WHT· ··    ·BLK·
·····       ·····       ·····
C is ALIVE (A·C) but WHITE · GC frees it · dangling pointer!
```

Go's Hybrid Barrier (Dijkstra + Yuasa, since Go 1.8)

```
writePointer(slot, new):
    shade(new)    // Dijkstra: if new is white · grey
    shade(*slot)  // Yuasa: if old is white · grey
    *slot = new   // actual pointer write
```

The barrier fires on every pointer store during concurrent mark phase.

GC Phase	Write Barrier Cost
Between GC cycles (sweep/idle)	OFF · zero overhead
Concurrent Mark	ON · ~5% throughput overhead

---

6. GC Pacing · GOGC and GOMEMLIMIT

Source: `runtime/mgc.go` ·`gcController`

GOGC · The Growth Ratio (default: 100)

```
GC trigger = live_heap × (1 + GOGC/100)
Live heap = 100MB:
  GOGC=100:  trigger at 200MB  (2× live)
  GOGC=200:  trigger at 300MB  (3× live)
  GOGC=50:   trigger at 150MB  (1.5× live)
  GOGC=off:  GC disabled
```

GOGC Value	GC Frequency	Tradeoff
50	Very frequent	Low memory, high CPU
100 (default)	Balanced	2× live heap, moderate CPU
200	Less frequent	3× live heap, lower CPU
off	Never	Unbounded memory, zero GC CPU

GOMEMLIMIT · Soft Memory Limit (Go 1.19+)

As heap approaches the limit, GC runs more aggressively (dynamically lowers GOGC).

```
  Heap                                                · container limit
(512MB)
  Size
  (MB)
   450 · ................... GOMEMLIMIT ........... · soft target
       ·        ..        GC more aggressive here
   400 ............. normal GOGC trigger
       ·    ·      ·
   300 ·  ·          ·
       ..              ·
```

```
   200 ·                  ···· live heap
       ·
     0 ····· time
```

```
# Container recipe (1GB limit):
GOMEMLIMIT=900MiB    # ~90% of container limit
GOGC=100             # or GOGC=off (GC runs only near limit)
```

Replaces the ballast pattern · no more allocating large `[]byte` to delay GC.

---

7. GC Phases and STW Pauses

```
  ··· One GC Cycle ···
  ··· ··· ··· ··· ···
  · Mark    · · Concurrent Marking    · · Mark    · · Concurrent   ·
  · Setup   · · GC + app together     · · Termin. · · Sweep        ·
  · (STW)   · · write barrier ON      · · (STW)   · ·              ·
  · <200·s  · · ~5% overhead          · · <200·s  · · lazy reclaim ·
  ··· ··· ··· ··· ···
```

Phase	Duration	What Happens
Mark Setup	<200·s STW	Enable write barrier, enqueue root scan jobs, resume goroutines
Concurrent Mark	ms to 100s of ms	GC goroutines (25% GOMAXPROCS) + mark assist from allocating Gs. Scan stacks, scan heap objects.
Mark Termination	<200·s STW	Drain remaining work, disable write barrier, compute next trigger
Concurrent Sweep	Until next cycle	Spans swept lazily on allocation. Returns pages to mheap / OS.

Mark assist: If a goroutine allocates faster than GC can mark, the runtime forces it to help mark objects before its allocation proceeds · latency spike on that G. Reduce allocations in hot paths to avoid the "mark assist tax."

---

8. sync.Pool · GC-Aware Object Reuse

Per-P object cache. Objects may be silently removed by GC · NOT a connection pool.

Source: `sync/pool.go` (registered with GC via `poolCleanup`)

Internal Structure

```
P0                  P1                  P2
·····               ·····               ·····

       ·                    ·                    ·
       ·                    ·                    ·
.............................................................
·     VICTIM CACHE (objects from previous GC cycle)         ·
·     Survive ONE more cycle, then dropped                  ·
.............................................................
```

Get/Put Flow

```
pool.Get():
  1. private (current P) ··· found? · return (no lock)
  2. shared (current P)  ··· found? · return (lock-free pop)
  3. steal other P's shared ·· found? · return
  4. victim cache ··********· found? · return
  5. pool.New() ************· fresh allocation
pool.Put(obj):
  1. private empty? · store there (no lock)
  2. else · append to shared (lock-free push)
```

GC Interaction · Two-Generation Scheme

Each GC cycle: current pools · victim cache, previous victim · dropped. Objects survive at most **two GC cycles** in the pool.

```
.......................................................................
· · Use For                       · · Don't Use For
·
.......................................................................
· Temporary byte buffers          · DB connection pools
·
· Serialization scratch space     · Objects with lifecycle/state
·
· bytes.Buffer / strings.Builder  · Anything requiring Close()
·
· Encoder/decoder state           · Objects that must persist across GC
·
.......................................................................
```

---

9. Profiling Memory

Heap Profile

```
go test -memprofile=mem.out -bench=BenchmarkXxx ./...
go tool pprof mem.out                   # interactive
go tool pprof -alloc_space mem.out      # total allocated (find hot
spots)
```

```
go tool pprof -inuse_space mem.out      # currently alive (find
leaks)
```

runtime.ReadMemStats

```
var m runtime.MemStats
runtime.ReadMemStats(&m)
// m.HeapAlloc    · bytes currently allocated (live objects)
// m.HeapSys      · bytes obtained from OS for heap
// m.NumGC        · completed GC cycles
// m.PauseTotalNs · total STW pause time
// m.Mallocs      · cumulative heap allocations
// m.Frees        · cumulative heap frees
```

GODEBUG=gctrace=1

```
GODEBUG=gctrace=1 ./myservice

gc 1 @0.012s 2%: 0.044+1.2+0.030 ms clock, 0.35+0.82/1.8/0.15+0.24
ms cpu, 4->4->2 MB, 4 MB goal, 8 P
                  ·          ·
·
                  ·          ·
·· heap: before·after·live
                  ·          ·· CPU time: assist/background/idle
                  ·· wall clock: STW1 + concurrent + STW2
```

Live Production Profiling

```
import _ "net/http/pprof"  // registers /debug/pprof/ endpoints
// ALWAYS behind authentication!

go tool pprof http://localhost:6060/debug/pprof/heap
go tool pprof -diff_base=before.out after.out  # compare snapshots
```

---

10. Common Memory Optimization Patterns

Pre-Allocate Slices and Maps

```
// BAD · repeated grow: 0·1·2·4·8·16·32·64·128
results := []User{}
for _, row := range rows { results = append(results,
parseUser(row)) }
// GOOD · single allocation
results := make([]User, 0, len(rows))
m := make(map[string]int, expectedSize)
```

Avoid String Concatenation in Loops

```
// BAD · O(n²)                        // GOOD · O(n)
```

```
s := ""
for _, item := range items {
    s += item.Name + ","
}
b.WriteByte(',') }
```

```
var b strings.Builder
b.Grow(len(items) * 20)
for i, item := range items {
    if i > 0 {

    b.WriteString(item.Name)
}
s := b.String()
```

Avoid fmt.Sprintf in Hot Paths

```
// BAD · 2+ allocs
key := fmt.Sprintf("user:%d", id)
strconv.Itoa(id)
```

```
// GOOD · 0-1 allocs
key := "user:" +
```

Reduce Pointer-Heavy Structures

```
// MORE GC WORK · every pointer scanned
values
type Record struct {
    Name    *string
    Tags    []*string
    Parent  *Record
}
```

```
// LESS GC WORK · inline

 type Record struct {
     Name     string
     Tags     []string
     ParentID int64
 }
```

Struct Field Ordering · Reduce Padding

```
  BadLayout (32B):                        GoodLayout (24B):
  ......................................  ................................
  ·a · 7pad  ·   b    ·c · 7pad  ·   d   ·  ·   b    ·   d    ·a ·c · 6pad ·
  ·1B·       ·  8B    ·1B·       ·  8B   ·  ·  8B    ·  8B    ·1B·1B·      ·
  ......................................  ................................
  bool,int64,bool,int64 = 32B               int64,int64,bool,bool =
24B (25% less)
```

---

11. Understanding Allocations with Benchmarks

b.ReportAllocs

```
func BenchmarkProcess(b *testing.B) {
    b.ReportAllocs()
    for i := 0; i < b.N; i++ { process(testData) }
}
// Output: BenchmarkProcess-8  1000000  1050 ns/op  256 B/op  3
allocs/op
```

testing.AllocsPerRun

```
func TestZeroAlloc(t *testing.T) {
    allocs := testing.AllocsPerRun(100, func() { fastPath(input) })
```

```
    if allocs > 0 { t.Errorf("expected zero allocs, got %f",
allocs) }
}
```

Zero-Allocation Hot Path Pattern

```
// Caller owns the buffer, reuses across calls
func formatKey(buf []byte, prefix string, id int) []byte {
    buf = buf[:0]                               // reset, keep
capacity
    buf = append(buf, prefix...)
    buf = append(buf, ':')
    buf = strconv.AppendInt(buf, int64(id), 10)
    return buf
}
```

Allocation Avoidance Quick Reference

```
.......................................................................
· Pattern That Allocates           · Zero-Alloc Alternative
  .
.......................................................................
· fmt.Sprintf("%d", n)             · strconv.Itoa(n) / AppendInt
  .
· fmt.Println(x)                   · io.WriteString(w, s)
  .
· return &localVar                 · return value type (copy)
  .
· interface conversion in hot path · use concrete type
  .
· append beyond cap                · pre-allocate: make([]T, 0, n)
  .
· errors.New("msg") per call       · package-level sentinel error
  .
· closure capturing variable       · pass as parameter instead
  .
.......................................................................
```

---

12. Quick Reference Card

```
ESCAPE ANALYSIS
...............
  Triggers: return &x, interface boxing, channel send, escaping
closure, too large
  Tools:    go build -gcflags='-m' ./...    (what escapes)
            go build -gcflags='-m -m' ./... (why it escapes)
MEMORY ALLOCATOR  (runtime/malloc.go)
................
  Tiny (<16B)  · packed into 16-byte blocks
  Small (·32KB) · mcache (per-P, no lock) · mcentral (locked) · mheap · OS
  Large (>32KB) · mheap directly · OS
```

```
GC PHASES  (runtime/mgc.go)
.........
  1. Mark Setup      · STW <200·s · enable write barrier
  2. Concurrent Mark · app + GC together, ~5% overhead
  3. Mark Termination · STW <200·s · disable write barrier
  4. Concurrent Sweep · reclaim dead objects, fully concurrent
  Total STW: typically <1ms per cycle
GC TUNING
.........
  GOGC=100 (default)   2× live heap.   Balanced.
  GOGC=50              1.5× live heap.  Less mem, more CPU.
  GOGC=200             3× live heap.    More mem, less CPU.
  GOMEMLIMIT=900MiB    Soft limit, GC aggressive near limit.
  Container: GOMEMLIMIT = container_memory × 0.9
PROFILING
.........
  go test -memprofile=mem.out -bench=.     # heap profile
  go tool pprof -alloc_space mem.out       # where allocs happen
  go tool pprof -inuse_space mem.out       # what's holding memory
  GODEBUG=gctrace=1 ./myservice            # per-cycle stats
  go test -benchmem -bench=. ./...         # allocs per op
OPTIMIZATION CHECKLIST
......................
  · Pre-allocate slices/maps with make(T, 0, n)
  · sync.Pool for temporary buffers
  · strings.Builder not += in loops
  · strconv not fmt.Sprintf in hot paths
  · Return values not pointers (avoid escape)
  · Concrete types in hot paths (avoid interface boxing)
  · Order struct fields by size (reduce padding)
  · b.ReportAllocs() in every benchmark
```

One-Line Summary

The compiler's escape analysis decides stack (~1ns) vs heap (~25-50ns) at build time; the concurrent tri-color GC reclaims heap with <1ms STW pauses; tune via `GOGC`/`GOMEMLIMIT`, profile with `pprof`/`gctrace`, and reduce allocations · every heap alloc you avoid is a direct throughput win.

---

pdqsort · Pattern-Defeating Quicksort

The algorithm Go's `slices.Sort` (and `sort.Slice`) uses under the hood since Go 1.19.

First, why not just use classic Quicksort?

Classic Quicksort is fast on average ·**O(n log n)** · but has a nasty worst case:

```
Already sorted input:  [1, 2, 3, 4, 5, 6, 7, 8]
Classic Quicksort with bad pivot choice · O(n²) ·
```

Real-world data is often **nearly sorted**, has **many duplicates**, or follows some pattern. Classic Quicksort falls apart on these.

---

pdqsort = 3 algorithms stitched together smartly

pdqsort is not one algorithm. It **detects the shape of your data** and picks the best tool for it.

```
.......................................................
·                     pdqsort                         ·
·                                                     ·
·   Is the slice tiny?  ··· Insertion Sort  O(n²)    ·
·                            (but tiny n, so fast)    ·
·                                                     ·
·   Is data nearly sorted? ··· HeapSort  O(n log n)  ·
·                               (bad pivot detected)  ·
·                                                     ·
·   Otherwise ··............· Quicksort  O(n log n)  ·
·                               (with smart pivot)    ·
.......................................................
```

The 3 ingredients

1. Insertion Sort (for tiny slices, n · 12)

```
[5, 3, 1, 4, 2]
Take each element, insert it into the right place:
[3, 5, 1, 4, 2]  · picked 3, inserted before 5
[1, 3, 5, 4, 2]  · picked 1, inserted at front
[1, 3, 4, 5, 2]  · picked 4, inserted after 3
[1, 2, 3, 4, 5]  · picked 2, inserted after 1
```

Why use it for small slices? Insertion sort has zero overhead (no recursion, no pivot logic). For n · 12, it beats everything.

---

2. Quicksort with Median-of-3 pivot (the main engine)

The key insight: **pivot choice determines everything**.

```
Bad pivot (always pick first):         Good pivot (median of 3):
[1, 2, 3, 4, 5]                        candidates: first=1, mid=3,
last=5
pivot = 1                               pivot = 3  · (the middle
value)
left  = []                              left  = [1, 2]
right = [2, 3, 4, 5]                    right = [4, 5]
· perfectly unbalanced ·               · balanced split ·
```

Median of 3: look at the first, middle, and last elements. Use the median as the pivot. This avoids the worst case on already-sorted data.

```
// Concept:
first, mid, last := data[0], data[n/2], data[n-1]
pivot := median(first, mid, last)
```

---

3. HeapSort as the escape hatch (when Quicksort misbehaves)

pdqsort **counts bad pivot choices**. If it detects too many (threshold: log·n), it switches to HeapSort.

```
Normal run:     Quicksort · Quicksort · Quicksort · done  ·
Pathological:   Quicksort · bad pivot · bad pivot · SWITCH TO HEAPSORT ·
```

HeapSort is always **O(n log n)** · never worse. It's slower than Quicksort on average, but it's the safety net that **guarantees** pdqsort never degrades to $O(n^2)$.

The "Pattern-Defeating" part

The name comes from its ability to **detect and exploit common patterns** in real data.

Pattern: Already sorted (or reverse sorted)

```
[1, 2, 3, 4, 5]  · ascending run detected
```

pdqsort checks if the data is already sorted (or reverse sorted) before doing anything. If yes · done or reverse in O(n).

Pattern: Many duplicates

```
[3, 3, 3, 1, 3, 3, 2, 3]
```

Uses a **3-way partition** (Dutch National Flag):

```
Left: elements < pivot  | Middle: elements == pivot  | Right:
elements > pivot
[1, 2]                  | [3, 3, 3, 3, 3]            | []
```

The middle "equal" section is never recursed into again · huge speedup for data with many duplicates.

The full decision tree

```
pdqsort(slice)
·
··· len · 12?
·   ··· InsertionSort · done
·
··· Check for sorted / reverse-sorted runs
·   ··· already sorted? · done (or reverse) · done
·
··· Pick pivot (median of 3)
·
··· 3-way partition:
·   ··· [< pivot] · recurse
```

```
·   ··· [= pivot] · skip (already in place)
·   ··· [> pivot] · recurse
·
··· Too many bad pivots? (counted internally)
    ··· Switch to HeapSort · guaranteed O(n log n)
```

Complexity Summary

Scenario	Time Complexity	Algorithm used
Tiny slice (n · 12)	$O(n^2)$ but tiny	Insertion Sort
Average case	O(n log n)	Quicksort
Already sorted	O(n)	Early exit
Many duplicates	O(n log n)	3-way Quicksort
Pathological input	O(n log n) **guaranteed**	HeapSort fallback
Space	O(log n)	Stack frames only

Why Go chose pdqsort

Before Go 1.19, Go used a hand-rolled introsort (intro = introspective). pdqsort replaced it because:

- **Faster on real data** · pattern detection avoids unnecessary work
- **Same worst-case guarantee** · O(n log n) always
- **Cache friendly** · insertion sort on small slices fits in CPU cache
- **Simpler to reason about** · clear separation of responsibilities

---

Key Takeaways

```
1. pdqsort = Quicksort + InsertionSort + HeapSort, combined
intelligently
2. It DETECTS the shape of your data and adapts:
   - Tiny? · InsertionSort
   - Sorted? · Early exit
   - Duplicates? · 3-way partition
   - Quicksort going bad? · HeapSort
3. Worst case is ALWAYS O(n log n) · never O(n²)
4. This is what slices.Sort() and sort.Slice() use in Go today
```

---

15 · Go Testing Internals: How `go test` Works Under the Hood

> *"There is no test framework. The* `go` *tool IS the framework."*

Most languages need a test runner (JUnit, pytest, NUnit, Jest). Go doesn't ·`go test` is baked into the toolchain. This document explains exactly what happens when you type `go test`, from file scanning to binary execution.

---

1. The Big Picture: No Magic, Just Code Generation

When you run `go test ./mypackage/`, the toolchain:

1. **Scans** `_test.go` files for test/benchmark/fuzz functions
2. **Generates** a hidden `_testmain.go` with a real `func main()`

3. **Compiles** everything into a temporary binary
4. **Executes** that binary

There is no reflection. No annotation processing. No runtime discovery. It's all **compile-time code generation** by the `go` tool.

---

2. The Four Gates: How Test Functions Are Discovered

Not every function in a `_test.go` file becomes a runnable test. The toolchain applies a strict 4-gate filter:

```
.............................................................
·  Gate 1: File name ends with _test.go                      ·
·    · Only these files are included in the test build.      ·
·    · go build ignores them entirely.                       ·
·                                                            ·
·  Gate 2: Function name starts with "Test"                  ·
·    · String prefix match, not type-system magic.           ·
·                                                            ·
·  Gate 3: Character after "Test" is uppercase or non-letter ·
·    · TestConfig ·  (uppercase 'C')                        ·
·    · Testconfig ·  (lowercase 'c' · silently ignored)     ·
·    · Test       ·  (no suffix · valid)                    ·
·    · Test_foo   ·  (underscore is non-letter · valid)     ·
·                                                            ·
·  Gate 4: Signature is exactly func(t *testing.T)           ·
·    · func TestFoo(t *testing.T)         · registered      ·
·    · func TestFoo(t *testing.T) error   · wrong return    ·
·    · func TestFoo()                     · missing param   ·
·    · func TestFoo(t testing.T)          · not a pointer   ·
.............................................................
```

Fail any gate · silently skipped. No errors, no warnings. This is deliberate · it lets you put test helpers right next to tests without annotation:

```
// This IS a test (passes all 4 gates):
func TestParseConfig(t *testing.T) { ... }
// This is NOT a test (fails Gate 3 · lowercase 'a'):
func TestableConfig() Config { ... }
// This is NOT a test (fails Gate 4 · wrong signature):
func TestHelper(input string) string { ... }
```

The Source Code Behind Gate 3

The actual check in `cmd/go/internal/load`:

```
func isTest(name, prefix string) bool {
    if !strings.HasPrefix(name, prefix) {
        return false
    }
    if len(name) == len(prefix) { // "Test" alone
        return true
    }
    r, _ := utf8.DecodeRuneInString(name[len(prefix):])
```

```
        return !unicode.IsLower(r)
    }
```

A single rune check at position `len("Test")`. That's the entire discovery logic.

---

3. The Generated `_testmain.go`

After scanning, `go test` generates a file that looks roughly like this:

```
package main
import (
    "os"
    "testing"
    "testing/internal/testdeps"
    _test "mypackage"  // your package under test
)
var tests = []testing.InternalTest{
    {"TestParseConfig", _test.TestParseConfig},
    {"TestValidate", _test.TestValidate},
    // every discovered TestXxx function
}
var benchmarks = []testing.InternalBenchmark{
    {"BenchmarkParse", _test.BenchmarkParse},
    // every discovered BenchmarkXxx function
}
var fuzzTargets = []testing.InternalFuzzTarget{
    // every discovered FuzzXxx function
}
func main() {
    m := testing.MainStart(testdeps.TestDeps{}, tests, benchmarks,
fuzzTargets)
    os.Exit(m.Run())
}
```

Key observations:

- It's a real `package main` with a real `main()`
- Your test functions are registered by **name** in a slice · no reflection
- `testing.MainStart` creates the test runner
- `m.Run()` executes tests and returns an exit code
- This file is generated, compiled, and deleted · you never see it

How to See It Yourself

```
# Compile the test binary without running it
go test -c -o /tmp/test_binary ./fundamentals/08_arrays_slices/
# Now you have a real executable:
file /tmp/test_binary
# Output: ELF 64-bit / Mach-O executable
# Run it manually with flags:
/tmp/test_binary -test.v -test.run TestReverseSlice
```

The `-test.v` and `-test.run` flags are parsed by the generated `main()` via the `testing` package. When you

use `go test -v -run Foo`, the tool translates those to `-test.v -test.run Foo` for the compiled binary.

---

4. The `_test.go` Compiler Boundary

Files ending with `_test.go` have a special status in the **compiler**, not just the test tool:

| Build command | `_test.go` files | Regular `.go` files | |---|---|---| | `go build` | · **Excluded** | · Included | | `go test` | · Included | · Included | | `go install` | · **Excluded** | · Included |

This is enforced at the **compiler level**, not by convention. Your test dependencies, test helpers, and test data types never leak into the production binary. Zero cost at runtime, zero bloat in deployment.

Why This Matters at Scale

In a large codebase with thousands of test files:

- Production binary size is unaffected by test code
- Test-only dependencies (mock types, test fixtures) don't pollute the dependency graph
- `go build` stays fast · it doesn't even parse test files

---

5. Two Test Package Modes: White-Box vs Black-Box

Go supports two package declarations in `_test.go` files:

White-Box Testing (same package)

```
// File: parser_test.go
package parser  // same package · access to unexported symbols
func TestInternalCache(t *testing.T) {
    c := newCache()       // · can access unexported newCache()
    c.set("key", "val")   // · can access unexported methods
}
```

Black-Box Testing (external test package)

```
// File: parser_test.go
package parser_test  // _test suffix · external package
import "mymodule/parser"
func TestPublicAPI(t *testing.T) {
    p := parser.New()     // · only exported API
    p.newCache()          // · compile error · unexported
}
```

The `_test` package suffix is special · the compiler allows it as the only exception to Go's "one package per directory" rule. Both packages coexist in the same directory but are compiled separately.

When to Use Which

| Mode | Use When | |---|---| | **White-box** (`package foo`) | Testing internal state, unexported helpers, edge cases in private logic | | **Black-box** (`package foo_test`) | Testing public API contracts, ensuring your API is usable, preventing test coupling to internals |

Enterprise recommendation: Use black-box tests for your public API surface, white-box tests for tricky internal algorithms. If you find yourself needing white-box access too often, your API surface might be too thin.

The `export_test.go` Backdoor

Sometimes you need black-box tests to access one internal symbol. The Go idiom:

```
// File: export_test.go (in package parser, NOT parser_test)
package parser
// Expose unexported symbols for testing only
var InternalNewCache = newCache

// File: parser_api_test.go (black-box)
package parser_test
func TestCacheBehavior(t *testing.T) {
    cache := parser.InternalNewCache()  // accessible via
export_test.go
}
```

Since `export_test.go` ends with `_test.go`, it's excluded from production builds. The stdlib uses this pattern extensively · check `strings/export_test.go` or `net/http/export_test.go`.

---

6. The `testing.T` Type: What It Actually Does

`*testing.T` isn't just a logger · it's a **test lifecycle controller**:

```
type T struct {
    common                     // embedded · shared with B
(benchmark) and F (fuzz)
    isParallel bool
    isEnvSet   bool
    context    *testContext     // controls parallel execution
}
type common struct {
    mu          sync.RWMutex
    output      []byte         // log buffer
    w           io.Writer
    ran         bool           // test was executed
    failed      bool           // test has failed
    skipped     bool           // test was skipped
    done        bool           // test is complete
    cleanups    []func()       // t.Cleanup() stack (LIFO)
    tempDir     string         // t.TempDir() path
    parent      *common        // parent test (for subtests)
    level       int            // nesting depth
    name        string         // full test name including parents
    // ...
}
```

Key Methods and What They Do Under the Hood

| Method | Behavior | |---|---| | `t.Errorf(...)` | Sets `failed = true`, appends to `output` buffer. **Does NOT stop the test.** | | `t.Fatalf(...)` | Sets `failed = true`, calls `runtime.Goexit()` · unwinds goroutine, runs

defers. | | `t.FailNow()` | Same as Fatal ·`runtime.Goexit()`. Must be called from test goroutine. | | `t.Parallel()` | Releases the test's slot, waits until parent completes, then runs concurrently with other parallel tests. | | `t.Run(name, f)` | Creates a child `*T`, runs `f` in a new goroutine. Parent waits for all children. | | `t.Cleanup(f)` | Pushes `f` onto a LIFO stack · runs after test completes (even on panic).||`t.TempDir()` | Creates a temp directory, auto-removed via `t.Cleanup()`. | | `t.Helper()` | Marks the calling function as a helper · error line numbers skip it. |

Why `t.Run()` Isolates Panics

```
func (t *T) Run(name string, f func(t *T)) bool {
    // Creates a NEW *T with its own failed/output state
    sub := &T{...}

    // Runs f in a new goroutine with panic recovery
    go func() {
        defer func() {
            if r := recover(); r != nil {
                // panic is caught HERE · only sub fails
                sub.Fail()
            }
        }()
        f(sub)
    }()

    // Parent waits for sub to finish
    <-sub.done
    return !sub.failed
}
```

This is exactly why we converted all table-driven tests to use `t.Run` · each subtest gets its own goroutine with its own recovery boundary.

---

7. Subtests: The `t.Run()` Architecture

Subtests create a **tree structure**:

```
TestMergeSorted                           (root)
··· TestMergeSorted/MergeSorted([1,3],[2,4])   (child)
··· TestMergeSorted/MergeSorted([],[1,2])       (child)
··· TestMergeSorted/MergeSorted([1],[])         (child)
```

Filtering with `-run`

The `-run` flag takes a `/`-separated regex matching this tree:

```
# Run only the empty-slice case:
go test -run "TestMergeSorted/MergeSorted\\(\\[\\]"
# Run all MergeSorted subtests:
go test -run "TestMergeSorted/"
# Run across test functions · any subtest containing "empty":
go test -run "/empty"
```

Parallel Subtests

```
func TestDatabase(t *testing.T) {
    tests := []struct{ name string; query string }{...}

    for _, tt := range tests {
        t.Run(tt.name, func(t *testing.T) {
            t.Parallel()  // this subtest runs concurrently with
siblings
            result := db.Query(tt.query)
            // ...
        })
    }
    // t.Run waits for ALL subtests before TestDatabase returns
}
```

`t.Parallel()` tells the runner: "I can run at the same time as other parallel subtests." The runner controls max parallelism via `-parallel` flag (default: `GOMAXPROCS`).

---

8. Benchmarks and Fuzz: Same Pattern, Different Gates

The same 4-gate system applies:

Benchmarks

```
Gate 1: _test.go file
Gate 2: Prefix "Benchmark"
Gate 3: Uppercase after prefix
Gate 4: Signature func(b *testing.B)

func BenchmarkMergeSorted(b *testing.B) {
    a := []int{1, 3, 5, 7, 9}
    x := []int{2, 4, 6, 8, 10}
    for i := 0; i < b.N; i++ {  // b.N is calibrated by the runner
        MergeSorted(a, x)
    }
}

go test -bench=BenchmarkMergeSorted -benchmem ./...
```

Fuzz (Go 1.18+)

```
Gate 1: _test.go file
Gate 2: Prefix "Fuzz"
Gate 3: Uppercase after prefix
Gate 4: Signature func(f *testing.F)

func FuzzParse(f *testing.F) {
    f.Add("valid input")              // seed corpus
    f.Fuzz(func(t *testing.T, s string) {
        result, err := Parse(s)
        if err != nil {
```

```
                return  // invalid input is fine
            }
            // Check invariants on valid parse results
            if result.String() != s {
                t.Errorf("round-trip failed: %q · %q", s,
result.String())
            }
        })
}
```

---

9. Test Binary Flags: The Hidden CLI

The compiled test binary accepts flags that `go test` translates:

| `go test` flag | Binary flag | Purpose | |---|---|---| | `-v` | `-test.v` | Verbose output | | `-run Foo` | `-test.run Foo` | Filter tests by regex | | `-bench .` | `-test.bench .` | Run benchmarks | | `-count 5` | `-test.count 5` | Repeat N times | | `-timeout 30s` | `-test.timeout 30s` | Timeout per test binary | | `-race` | (compiler flag) | Enable race detector | | `-cover` | `-test.coverprofile` | Coverage analysis | | `-cpuprofile f` | `-test.cpuprofile f` | CPU profiling | | `-memprofile f` | `-test.memprofile f` | Memory profiling | | `-trace f` | `-test.trace f` | Execution tracing |

Using the Binary Directly (Advanced)

```
# Compile without running
go test -c -o mytest ./mypackage/
# Run on a different machine, in a container, under strace, etc.
./mytest -test.v -test.run TestCriticalPath
# Profile in production-like environment
./mytest -test.bench . -test.cpuprofile cpu.out -test.memprofile
mem.out
```

This is invaluable for debugging CI failures · compile locally, ship the binary to the CI environment, run with verbose flags.

---

10. Comparison with Other Languages

| Aspect | Go | Java (JUnit 5) | Python (pytest) | C# (xUnit) | |---|---|---|---|---| | Discovery | Naming convention + signature | `@Test` annotation | `test_` prefix + function | `[Fact]`/`[Theory]` attributes | | Mechanism | Compile-time code gen | Runtime reflection | Runtime import + inspect | Runtime reflection | | Runner | Built into `go` tool | External (Maven/Gradle) | External (`pytest` CLI) | External (`dotnet test`) | | Test file separation | `_test.go` (compiler enforced) | Convention (`src/test/`) | Convention (`test_*.py`) | Convention (`*.Tests.csproj`) | | Framework needed | No (stdlib `testing`) | Yes (JUnit jar) | Yes (pytest package) | Yes (xUnit NuGet) | | Reflection used | Never | Yes (`@Test` scanning) | Yes (`inspect` module) | Yes (attribute scanning) | | Parallel by default | No (opt-in `t.Parallel()`) | No (opt-in) | No (via `pytest-xdist`) | Yes (per-collection) |

Go's philosophy: The test infrastructure is part of the language toolchain, not an ecosystem add-on. No framework to install, no runner to configure, no build plugin to wire up. `go test` just works.

---

11. Production Testing Workflow

```
# Basic: run all tests
go test ./...
# With race detector (non-negotiable in CI)
go test -race ./...
# Verbose with specific test
go test -v -run TestMergeSorted ./fundamentals/08_arrays_slices/
# Coverage report
go test -coverprofile=coverage.out ./...
go tool cover -html=coverage.out -o coverage.html
# Benchmark with memory stats
go test -bench=. -benchmem ./...
# Compare benchmarks (install benchstat first)
go test -bench=. -count=10 ./... > old.txt
# ... make changes ...
go test -bench=. -count=10 ./... > new.txt
benchstat old.txt new.txt
# CPU profile a specific benchmark
go test -bench=BenchmarkHotPath -cpuprofile=cpu.out ./...
go tool pprof cpu.out
# Execution trace (visual goroutine timeline)
go test -trace=trace.out -run TestConcurrent ./...
go tool trace trace.out
```

---

12. Key Takeaways

1. `go test` **generates** `main()` **for you** · no test framework, no runner, no reflection
2. **4-gate filter**: `_test.go` · `Test` prefix · uppercase after prefix · correct signature
3. `_test.go` **is compiler-enforced** · never in production binary, not just convention
4. `t.Run()` **creates isolated goroutines** · panics in subtests don't kill siblings
5. **Two package modes**: `package foo` (white-box) vs `package foo_test` (black-box)
6. **Test binaries are real executables** · you can `go test -c` and ship them for remote debugging
7. **Same pattern for all**: `TestXxx`, `BenchmarkXxx`, `FuzzXxx` · same gates, different types

> *"The simplicity is the sophistication. There's no test framework to learn, no runner to configure, no plugin to install. You write a function with the right name and signature, and Go does the rest."*

1. Go's Built-In Deadlock Detector · And Why It's Not Enough

Go's runtime includes a narrow deadlock detector. It fires when **all** goroutines are asleep simultaneously:

```
func main() {
    ch := make(chan int)
    <-ch   // only goroutine blocks · runtime detects deadlock
}
// fatal error: all goroutines are asleep - deadlock!
```

Why It Almost Never Fires in Production

```
func main() {
    ch := make(chan int)
    go func() { time.Sleep(time.Hour) }()  // one goroutine "alive"
    <-ch   // blocks forever · NO detection
}
// Runtime: "G2 is sleeping on timer, not stuck · not a deadlock"
```

In production, HTTP servers, background workers, and timers are always running, so the all-goroutines-asleep condition never triggers.

```
.......................................................................
·  Go's deadlock detector:
·
·  · Catches: ALL goroutines blocked (toy programs, tests)          ·
·  · Misses:  ONE goroutine blocked while others run (production)    ·
·  · Misses:  Goroutine leaks (blocked goroutines that pile up)      ·
·  · Cannot:  Predict future deadlocks at compile time               ·
·
·
```

```
·  This is equivalent to the Halting Problem · unsolvable in general. ·
·  Go's answer: give you TOOLS to find problems, not prevention.
·
.......................................................................
```

What Go Provides Instead

```
Tool                          What It Finds
............................  ........................................
context.WithTimeout()         YOUR code sets a deadline
(prevention)
go test -race                 Data races (not deadlocks)
runtime.NumGoroutine()        Goroutine count growth (leak
detection)
pprof goroutine profile       WHERE goroutines are stuck
(diagnosis)
go tool trace                 VISUAL timeline of blocking
(diagnosis)
GODEBUG=schedtrace=1000       Scheduler state snapshots (diagnosis)
goleak (uber library)         Test-time goroutine leak detection
```

---

2. pprof · The Swiss Army Knife

`pprof` is Go's built-in profiling system. It's in the standard library · no external tools needed.

Two Ways to Use pprof

```
1. FROM TESTS (development):
   go test -cpuprofile=cpu.out -bench=.
   go tool pprof cpu.out
2. FROM A RUNNING SERVER (production):
   import _ "net/http/pprof"    // register handlers
   go http.ListenAndServe(":6060", nil)

   go tool pprof
http://localhost:6060/debug/pprof/profile?seconds=30
```

Available Profiles

```
.......................................................................
· Profile              · What It Measures
 ·
.......................................................................
· /debug/pprof/profile · CPU: where is time spent? (sampling-based)
·
· /debug/pprof/heap    · Memory: what allocated? what's still alive?
 ·
· /debug/pprof/goroutine · Goroutines: where are they? what are they
doing? ·
· /debug/pprof/block   · Blocking: where do goroutines wait?
·
```

```
· /debug/pprof/mutex   · Mutex: where is lock contention?
·
· /debug/pprof/threadcreate · OS threads: how many created?
·
· /debug/pprof/allocs  · Allocations: all allocations (past + present)
·
· /debug/pprof/trace   · Execution trace: full goroutine timeline
·
.......................................................................
```

pprof Navigation Commands

```
$ go tool pprof cpu.out
(pprof) top 10          # top 10 functions by CPU time
(pprof) top -cum        # top by cumulative time (includes callees)
(pprof) list funcName   # source-annotated view of a specific
function
(pprof) web             # open interactive graph in browser
(pprof) peek funcName   # show callers and callees of a function
(pprof) disasm funcName # assembly-level view
```

Web UI (Recommended)

```
go tool pprof -http=:8080 cpu.out
# Opens browser with interactive flame graph, source view, graph
view
```

---

3. CPU Profiling · Find What's Slow

From Tests

```
# Profile a specific benchmark
go test -cpuprofile=cpu.out -bench=BenchmarkProcess ./...
go tool pprof -http=:8080 cpu.out
# Profile all tests (useful for slow test suites)
go test -cpuprofile=cpu.out -run=TestSlow ./...
go tool pprof cpu.out
```

From Production

```
import _ "net/http/pprof"
// In main() or init():
go func() {
    // IMPORTANT: bind to localhost or internal network only!
    log.Println(http.ListenAndServe("localhost:6060", nil))
}()

# Capture 30 seconds of CPU profile:
go tool pprof http://localhost:6060/debug/pprof/profile?seconds=30
# Or save to file:
```

```
curl -o cpu.out
http://localhost:6060/debug/pprof/profile?seconds=30
go tool pprof -http=:8080 cpu.out
```

How CPU Profiling Works Internally

```
The runtime sets a timer (SIGPROF on Unix) that fires 100
times/second.
Each tick:
  1. Interrupt the current goroutine
  2. Capture its full stack trace
  3. Store in profile buffer
After N seconds, you have N×100 stack samples.
Functions that appear in many samples = spending more CPU time.
This is SAMPLING · not tracing. Overhead is ~1-3%. Safe for
production.
```

Reading CPU Profile Output

```
(pprof) top 5
Showing nodes accounting for 4.2s, 84% of 5s total
      flat  flat%   sum%        cum   cum%
     1.8s 36.00% 36.00%      1.8s 36.00%  runtime.memmove
     0.9s 18.00% 54.00%      2.1s 42.00%
encoding/json.(*Decoder).Decode
     0.6s 12.00% 66.00%      0.6s 12.00%  runtime.mallocgc
     0.5s 10.00% 76.00%      0.5s 10.00%  syscall.Syscall
     0.4s  8.00% 84.00%      3.5s 70.00%  main.handleRequest
flat  = time spent IN this function (excluding callees)
cum   = time spent IN this function + all functions it calls

When flat · cum  · this function IS the bottleneck (doing the work
itself)
When flat << cum · this function CALLS the bottleneck (look at its
callees)
```

---

4. Memory Profiling · Find What Allocates

From Tests

```
go test -memprofile=mem.out -bench=BenchmarkProcess ./...
go tool pprof -http=:8080 mem.out
```

Four Memory Views

```
.........................................................................
· View              · What It Shows
  ·
.........................................................................
· inuse_space       · Bytes currently allocated (what's alive right now)
```

```
  .
·                  · · Find memory leaks, large allocations
  .
.......................................................................
· inuse_objects    · Number of objects currently alive
   .
·                  · · Find object count issues (too many small
objects)   ·
.......................................................................
· alloc_space      · Total bytes allocated over time (including freed)
  .
·                  · · Find GC pressure sources (hot allocation paths)
  .
.......................................................................
· alloc_objects    · Total number of allocations over time
   .
·                  · · Find allocation-heavy code (even if objects are
   .
·                  ·   small, many allocs = GC pressure)
  .
.......................................................................

# Switch between views in pprof:
(pprof) sample_index = inuse_space     # what's alive now (default)
(pprof) sample_index = alloc_space     # total allocated over time
(pprof) top 10
```

Combining with Escape Analysis

```
# Step 1: Find what allocates (pprof)
go test -memprofile=mem.out -bench=. && go tool pprof mem.out
# Step 2: Find WHY it allocates (escape analysis)
go build -gcflags='-m' ./...
# ./handler.go:42:6: moved to heap: result   · compiler tells you WHY
# Step 3: Verify fix with benchmarks
go test -bench=BenchmarkProcess -benchmem ./...
# BenchmarkProcess-8   500000   3200 ns/op   256 B/op   4 allocs/op
#                                                 .          .
#                                       bytes allocated   number of
heap allocs
```

---

5. Goroutine Profiling · Find What's Stuck

This is your primary tool for finding **blocked goroutines** and **goroutine leaks**.

Quick Count Check

```
# From a running server:
curl http://localhost:6060/debug/pprof/goroutine?debug=1 | head -1
# goroutine profile: total 847
# If this number grows monotonically · you have a goroutine leak
```

Full Goroutine Dump

```
# Human-readable dump of ALL goroutine stacks:
curl http://localhost:6060/debug/pprof/goroutine?debug=2
```

Output:

```
goroutine 4821 [chan receive, 47 minutes]:
main.processOrder.func1()
    /app/handler.go:142 +0x8c
goroutine 4822 [chan receive, 47 minutes]:
main.processOrder.func1()
    /app/handler.go:142 +0x8c
goroutine 4823 [chan receive, 46 minutes]:
main.processOrder.func1()
    /app/handler.go:142 +0x8c

Red flags in goroutine dumps:
  [chan receive, 47 minutes]     · blocked on channel for 47 min
  [chan send, 2 hours]           · blocked trying to send for 2 hours
  [select, 30 minutes]          · stuck in select for 30 min
  [semacquire, 15 minutes]      · waiting for mutex for 15 min
  [IO wait, 1 hour]             · stuck on I/O for 1 hour
  Healthy goroutines show:
  [running]                     · actively executing
  [sleep]                       · time.Sleep (intentional)
  [IO wait, 50ms]               · normal network I/O
  [chan receive]                 · no duration = just started waiting
```

Grouped View (pprof)

```
go tool pprof http://localhost:6060/debug/pprof/goroutine
(pprof) top 10
# Shows which functions have the most goroutines stuck in them
(pprof) list processOrder
# Source-level view: which LINE has goroutines blocked
```

---

6. Block & Mutex Profiling · Find Contention

Block Profiling · Where Goroutines Wait

```
// Enable block profiling (not enabled by default · has overhead):
runtime.SetBlockProfileRate(1)  // 1 = record every blocking event
                                // N = sample 1 in N events (for
production)

go tool pprof http://localhost:6060/debug/pprof/block
(pprof) top 5
# Shows: which operations cause goroutines to WAIT the longest
# Typical findings: channel receives, mutex locks, select
```

```
statements
```

Mutex Profiling · Where Locks Compete

```
// Enable mutex profiling:
runtime.SetMutexProfileFraction(1)  // 1 = record every contention
event

go tool pprof http://localhost:6060/debug/pprof/mutex
(pprof) top 5
# Shows: which mutexes have the most contention (multiple
goroutines
# trying to acquire the same lock simultaneously)
```

When to Use Each

```
"My service is slow"
··· CPU profile shows low CPU usage
·   ··· Block profile · goroutines waiting on channels/IO
·   ··· Mutex profile · goroutines fighting over locks
··· CPU profile shows high CPU usage
    ··· CPU profile · which function is hot
```

---

7. go tool trace · The Visual Timeline

`go tool trace` gives you a **visual, interactive timeline** of everything the runtime does: goroutine scheduling, GC pauses, syscalls, network I/O, blocking.

Capture a Trace

```
# From tests:
go test -trace=trace.out -bench=. ./...
go tool trace trace.out
# From production (short capture):
curl -o trace.out http://localhost:6060/debug/pprof/trace?seconds=5
go tool trace trace.out
# Programmatically:
import "runtime/trace"
f, _ := os.Create("trace.out")
trace.Start(f)
defer trace.Stop()
```

What the Trace Shows

```
.......................................................................
·  Timeline (horizontal = time, vertical = goroutines/procs)
·
·
·
·  Proc 0: ··G1··********G3******GC****G1****                        ·
·  Proc 1: ******G2**************GC******G4****                      ·
```

```
·  Proc 2: ··G5·····syscall·····G5····                    ·
·
·
·  ·· = running                                            ·
·  ·· = idle (no goroutine scheduled on this P)            ·
·  GC = garbage collection (STW phases shown in red)
·
·  syscall = goroutine in syscall (detached from P)
·
·
·
·  Click any block to see: goroutine ID, function, stack trace,
·
·  why it was blocked, how long it ran, what unblocked it.
·
.....................................................................
```

What to Look For

```
Problem                      What Trace Shows
.........................    ........................................
Latency spikes               Long GC pauses (red STW bars)
Underutilization             Many idle procs (not enough goroutines)
Lock contention              Goroutines blocked on sync events
Channel bottleneck           Many goroutines blocked on same channel
Scheduling delays            Long gaps between runnable · running
Syscall storms               Many goroutines in syscall
simultaneously
```

pprof vs trace · When to Use Which

```
pprof:  "WHERE is the problem?" (statistical, low overhead,
production-safe)
        · Use for: CPU hotspots, memory leaks, goroutine counts
trace:  "WHAT HAPPENED and WHEN?" (deterministic, higher overhead,
short captures)
        · Use for: latency investigation, scheduler behavior, GC
impact, concurrency bugs
```

---

8. GODEBUG · Runtime Diagnostic Flags

Environment variables that make the Go runtime print diagnostic information. Zero code changes needed · just set the variable before running.

GC Tracing

```
GODEBUG=gctrace=1 ./myapp
```

Output:

```
gc 1 @0.012s 2%: 0.021+0.54+0.003 ms clock, 0.17+0.32/0.41/0+0.025
ms cpu, 4->4->1 MB, 4 MB goal, 0 MB stacks, 0 MB globals, 8 P
```

```
.   .      .    .                     .                                    .
          .             .
.   .      .    .                     .                                    .
          .             ··· GOMAXPROCS
.   .      .    .                     .                                    .
          ··· goal heap size
.   .      .    .                     .                                    ···
heap: before·after·live
.   .      .    .                     ··· CPU time: assist/background/idle
.   .      .    ··· wall clock: STW1+concurrent+STW2
.   .      ··· % of CPU used for GC
.   ··· time since program start
··· GC cycle number
```

What to look for:

- `2%` · GC using 2% of CPU · healthy
- `25%` · GC using 25% of CPU · too much allocation, reduce heap pressure
- `STW` phases > 1ms · investigate large pointer-heavy data structures
- `before·after·live` · `live` keeps growing · memory leak

Scheduler Tracing

```
GODEBUG=schedtrace=1000 ./myapp      # print every 1000ms
GODEBUG=schedtrace=1000,scheddetail=1 ./myapp  # detailed per-P
info
```

Output:

```
SCHED 1004ms: gomaxprocs=8 idleprocs=6 threads=10 spinningthreads=0
  idlethreads=5 runqueue=0 [0 0 0 0 0 0 0 0]
                                                  ··· per-P local run
queue lengths
                            ··· global run queue length
               ··· how many Ps are idle (6 of 8 = underutilized)
```

What to look for:

- `idleprocs=7` of `gomaxprocs=8` · only 1 P is busy · not enough parallelism
- `runqueue=500 [100 50 200 ...]` · goroutines piling up, can't keep up
- `threads=200` · too many OS threads · goroutines stuck in syscalls

Other Useful GODEBUG Flags

```
GODEBUG=madvdontneed=1     # return memory to OS more aggressively
(Linux)
GODEBUG=asyncpreemptoff=1  # disable async preemption (debugging
only)
GODEBUG=invalidptr=1       # crash on invalid pointer (finding
corruption)
GODEBUG=cgocheck=2         # strict cgo pointer checks
```

---

9. dlv (Delve) · The Interactive Debugger

Delve is Go's purpose-built debugger. It understands goroutines, channels, interfaces, and defer stacks · unlike GDB which doesn't.

Installation

```
go install github.com/go-delve/delve/cmd/dlv@latest
```

Basic Usage

```
# Debug a program:
dlv debug ./cmd/server
# Debug a test:
dlv test ./pkg/handler -- -test.run TestProcess
# Attach to running process:
dlv attach <PID>
# Core dump analysis:
dlv core ./myapp core.12345
```

Essential Commands

```
(dlv) break main.handleRequest    # set breakpoint
(dlv) break handler.go:42         # breakpoint at line
(dlv) condition 1 id == 42        # conditional breakpoint
(dlv) continue                    # run until breakpoint
(dlv) next                        # step over (next line)
(dlv) step                        # step into function call
(dlv) stepout                     # step out of current function
(dlv) print myVar                 # inspect variable
(dlv) print *myPointer            # dereference pointer
(dlv) locals                      # show all local variables
(dlv) args                        # show function arguments
(dlv) stack                       # show stack trace
(dlv) goroutines                  # list ALL goroutines
(dlv) goroutine 15                # switch to goroutine 15
(dlv) goroutine 15 stack          # stack of specific goroutine
```

Debugging Goroutines

```
(dlv) goroutines
  Goroutine 1 - User: main.main (main.go:15) (thread 12345)
  Goroutine 5 - User: main.worker (worker.go:42) [chan receive]
  Goroutine 6 - User: main.worker (worker.go:42) [chan receive]
  Goroutine 7 - User: main.processor (proc.go:18) [running]

  [chan receive] = blocked on channel · dlv shows you the state!

(dlv) goroutine 5          # switch to goroutine 5
(dlv) stack                # see its full call stack
(dlv) frame 2              # navigate to frame 2 in the stack
(dlv) locals               # see local variables in that frame
(dlv) print ch             # inspect the channel it's blocked on
```

Debugging Channel State

```
(dlv) print ch
chan int {
    qcount: 3,          # 3 values in buffer
    dataqsiz: 5,        # buffer capacity = 5
    buf: *[5]int{10, 20, 30, 0, 0},  # buffer contents
    closed: 0,          # not closed
    sendx: 3,           # next send index
    recvx: 0,           # next receive index
    recvq: waitq{...},  # waiting receivers
    sendq: waitq{...},  # waiting senders
}
```

When to Use dlv vs pprof

```
dlv:   "I need to inspect SPECIFIC STATE at a SPECIFIC MOMENT"
       · Breakpoints, variable inspection, step-through
       · Use for: logic bugs, unexpected values, control flow issues
pprof: "I need to find PATTERNS across the WHOLE PROGRAM"
       · Statistical profiling, aggregate views
       · Use for: performance issues, memory leaks, goroutine leaks
```

---

10. Goroutine Leak Detection

A goroutine leak is when goroutines are created but never exit · they pile up over time, consuming memory and eventually crashing the process.

Common Leak Patterns

```
// Leak 1: Sending to a channel nobody reads
func leak1() {
    ch := make(chan int)
    go func() {
        result := expensiveWork()
        ch <- result      // blocks forever if nobody reads ch
    }()
    // ch goes out of scope but goroutine is stuck on send
}
// Leak 2: Receiving from a channel nobody writes to or closes
func leak2() {
    ch := make(chan int)
    go func() {
        for v := range ch {  // waits forever · ch is never closed
            process(v)
        }
    }()
}
// Leak 3: Missing context cancellation
func leak3() {
```

```
    go func() {
        ticker := time.NewTicker(time.Second)
        for range ticker.C {
            doWork()     // runs forever · no stop condition
        }
    }()
}
```

Detection in Tests · goleak

```
import "go.uber.org/goleak"
func TestMain(m *testing.M) {
    goleak.VerifyTestMain(m)    // fails if goroutines leak between
tests
}
// Or per-test:
func TestProcess(t *testing.T) {
    defer goleak.VerifyNone(t)
    // ... test code ...
}
```

Detection in Tests · Manual

```
func TestNoLeak(t *testing.T) {
    before := runtime.NumGoroutine()

    // ... exercise the code ...

    time.Sleep(100 * time.Millisecond)  // let goroutines settle
    after := runtime.NumGoroutine()

    if after > before {
        t.Errorf("goroutine leak: before=%d after=%d", before,
after)
        // Dump goroutine stacks for debugging:
        buf := make([]byte, 1<<20)
        n := runtime.Stack(buf, true)  // true = all goroutines
        t.Logf("goroutine dump:\n%s", buf[:n])
    }
}
```

Detection in Production · Metrics

```
// Expose as Prometheus metric:
prometheus.NewGaugeFunc(prometheus.GaugeOpts{
    Name: "go_goroutines",
    Help: "Number of goroutines that currently exist.",
}, func() float64 {
    return float64(runtime.NumGoroutine())
})
// Alert rule (Prometheus):
// ALERT GoroutineLeak
```

```
//   IF go_goroutines > 10000
//   OR rate(go_goroutines[5m]) > 10
//   FOR 5m
```

Prevention Patterns

```
// ALWAYS pair goroutine creation with a cancellation mechanism:
// Pattern 1: Context cancellation
func safeWorker(ctx context.Context) {
    for {
        select {
        case <-ctx.Done():
            return          // exits when context cancelled
        case job := <-jobs:
            process(job)
        }
    }
}
// Pattern 2: Done channel
func safeProducer(done <-chan struct{}) <-chan int {
    out := make(chan int)
    go func() {
        defer close(out)
        for i := 0; ; i++ {
            select {
            case <-done:
                return      // exits when done closed
            case out <- i:
            }
        }
    }()
    return out
}
// Pattern 3: Buffered channel (prevents send-side leak)
func safeOneShot() <-chan Result {
    ch := make(chan Result, 1)     // buffer of 1!
    go func() {
        ch <- expensiveWork()     // even if nobody reads,
goroutine exits
    }()                           // because buffer absorbs the
value
    return ch
}
```

---

11. Production Profiling · Safe Practices

Security: Don't Expose pprof to the Internet

```
// · DANGEROUS · pprof accessible from anywhere:
go http.ListenAndServe(":6060", nil)
// · SAFE · bind to localhost only:
```

```
go http.ListenAndServe("localhost:6060", nil)
// · SAFE · separate mux with auth middleware:
debugMux := http.NewServeMux()
debugMux.HandleFunc("/debug/pprof/", pprof.Index)
debugMux.HandleFunc("/debug/pprof/profile", pprof.Profile)
debugMux.HandleFunc("/debug/pprof/trace", pprof.Trace)
// ... add authentication middleware ...
go http.ListenAndServe("localhost:6060", authMiddleware(debugMux))
```

Performance Impact

```
.......................................................................
· Profile Type            · Overhead     · Production-Safe?           ·
.......................................................................
· CPU profile             · ~1-3%        · · Yes (sampling-based)     ·
· Heap profile            · ~0%          · · Yes (always collected)   ·
· Goroutine profile       · ~0%          · · Yes (snapshot)           ·
· Block profile           · ~5-10%       · ··  Rate-limit in prod     ·
· Mutex profile           · ~5-10%       · ··  Rate-limit in prod     ·
· Execution trace         · ~10-20%      · ··  Short captures only    ·
.......................................................................
```

Continuous Profiling in Production

```
// Pattern: periodic profile capture for monitoring platforms
func startContinuousProfiling(ctx context.Context) {
    ticker := time.NewTicker(1 * time.Minute)
    defer ticker.Stop()

    for {
        select {
        case <-ctx.Done():
            return
        case <-ticker.C:
            // Capture 10-second CPU profile
            f, _ := os.CreateTemp("", "cpuprof-*.out")
            pprof.StartCPUProfile(f)
            time.Sleep(10 * time.Second)
            pprof.StopCPUProfile()
            f.Close()
            uploadToMonitoring(f.Name())
            os.Remove(f.Name())
        }
    }
}
```

Services like **Google Cloud Profiler**, **Datadog Continuous Profiler**, and **Pyroscope** automate this · they continuously sample and aggregate profiles.

  go run -race ./cmd/server            # during development
```

One-Line Summary

Go has no compile-time deadlock prevention · instead it gives you `pprof` for profiling (CPU, memory, goroutines, contention), `go tool trace` for visual timelines, `GODEBUG` for runtime diagnostics, `dlv` for interactive debugging, and `goleak` for test-time leak detection. Your job is to use them.

Deep Dive: Production Go · Pitfalls, Library Choices & Enterprise Patterns

---

1. The Top 15 Go Production Pitfalls

Pitfall #1 · Goroutine Leak (blocked on channel, no cancellation)

The Bug:

```
func fetch(url string) <-chan string {
    ch := make(chan string)
    go func() {
        resp, _ := http.Get(url)           // blocks forever if
server hangs
        defer resp.Body.Close()
        body, _ := io.ReadAll(resp.Body)
        ch <- string(body)                 // blocks forever if
nobody reads
    }()
    return ch
}
```

Why it happens: The goroutine has no way to be told "stop waiting." If the caller abandons the channel or the HTTP request hangs, the goroutine lives forever. Each leaked goroutine holds its stack (~2-8 KB), plus any heap objects it references · including the `http.Response`, its TLS buffers, and the TCP connection. At scale, thousands

of leaked goroutines cause OOM.

How to detect:

```
.............................................................
·  runtime.NumGoroutine()    · monitor in /debug/vars       ·
·  pprof goroutine profile   · GET /debug/pprof/goroutine   ·
·  go tool pprof             · list goroutines by function  ·
·  goleak (uber-go/goleak)   · fails tests on goroutine leak·
.............................................................
```

How to fix: Always pass `context.Context` and `select` on `ctx.Done()`:

```
func fetch(ctx context.Context, url string) (string, error) {
    req, err := http.NewRequestWithContext(ctx, "GET", url, nil)
    if err != nil {
        return "", err
    }
    resp, err := http.DefaultClient.Do(req)
    if err != nil {
        return "", err
    }
    defer resp.Body.Close()
    body, err := io.ReadAll(resp.Body)
    return string(body), err
}
```

Pitfall #2 · Nil Interface Trap (typed nil vs true nil)

The Bug:

```
func getError() error {
    var err *MyError = nil       // typed nil pointer
    return err                   // wraps in iface{*itab, nil} · NOT
nil!
}
if getError() != nil {           // TRUE · even though the value is
nil
    fmt.Println("unexpected!")   // this runs
}
```

Why it happens: An interface is a two-word struct `{type, data}`. When you assign a typed nil pointer, the type word is non-nil (it points to `*MyError`'s type info). `== nil` only returns true when BOTH words are zero.

```
var err *MyError = nil       var err error = nil
.......................      .......................
· *MyError ·   nil    ·      ·   nil    ·   nil    ·
.......................      .......................
err == nil · FALSE ·          err == nil · TRUE ·
(type word is non-nil)        (both words are nil)
```

How to fix: Never return a concrete typed nil from a function that returns an interface. Return the bare `nil`:

```
func getError() error {
    var err *MyError = validate()
```

```
    if err != nil {
        return err          // only return if non-nil
    }
    return nil              // return untyped nil
}
```

Pitfall #3 · Slice Backing Array Memory Leak

The Bug:

```
var bigSlice = make([]byte, 1<<20)  // 1 MB
func first10() []byte {
    return bigSlice[:10]            // returns 10 bytes, holds 1 MB
in memory
}
```

Why it happens: A slice header is `{pointer, len, cap}`. Sub-slicing shares the backing array. The GC cannot free the 1 MB array because the 10-byte slice still references it.

```
bigSlice[:10]
.............................
· ptr ......................................................
· len = 10 ·   · 10 bytes used · ~~~ 1MB-10 wasted ~~~  ·
· cap = 1M ·   ........................................
............   backing array pinned by ptr · GC can't free it
```

How to fix: Copy the data to detach from the backing array:

```
func first10() []byte {
    result := make([]byte, 10)
    copy(result, bigSlice[:10])
    return result                   // new 10-byte backing array
}
```

Pitfall #4 · Map Never Shrinks

The Bug:

```
m := make(map[int]string)
for i := 0; i < 1_000_000; i++ {
    m[i] = "data"
}
for i := 0; i < 1_000_000; i++ {
    delete(m, i)
}
// m now has 0 entries, but the internal bucket array is still
sized for 1M entries
```

Why it happens: `runtime.hmap` allocates buckets in powers of 2. Deleting keys marks slots as empty (`tophash = emptyOne`) but NEVER deallocates bucket memory. The only way to reclaim is to create a new map and copy surviving entries.

How to detect: `runtime.ReadMemStats()` · watch `HeapInuse` after bulk deletes.

How to fix: Periodically rebuild the map, or use a map of pointers where the pointed-to values can be GC'd independently:

```
// Rebuild to reclaim memory
newMap := make(map[int]string, len(m))
for k, v := range m {
    newMap[k] = v
}
m = newMap
```

Pitfall #5 · `time.After` in Loops (timer leak)

The Bug:

```
for {
    select {
    case msg := <-ch:
        handle(msg)
    case <-time.After(5 * time.Second):  // NEW timer every
iteration · never GC'd until fired
        log.Println("timeout")
    }
}
```

Why it happens: `time.After` creates a `*time.Timer` that cannot be garbage collected until it fires. In a hot loop processing thousands of messages/sec, this creates thousands of live timers, each holding a goroutine in the runtime timer heap.

How to fix: Reuse a single timer with `time.NewTimer` + `Reset`:

```
timer := time.NewTimer(5 * time.Second)
defer timer.Stop()
for {
    timer.Reset(5 * time.Second)
    select {
    case msg := <-ch:
        handle(msg)
    case <-timer.C:
        log.Println("timeout")
    }
}
```

Pitfall #6 · Forgetting to Check Error from `defer Close/Flush`

The Bug:

```
func writeFile(path string, data []byte) error {
    f, err := os.Create(path)
    if err != nil {
        return err
    }
    defer f.Close()                 // error from Close is silently
swallowed!
```

```
    w := bufio.NewWriter(f)
    w.Write(data)
    return w.Flush()                // Flush succeeds, but Close
may fail (disk full, NFS)
}
```

Why it happens: `defer` executes after the return statement. If `Close()` returns an error (disk full, network filesystem timeout), it's silently discarded. Buffered writers may not flush their last buffer until `Close`.

How to fix: Use a named return to capture the deferred error:

```
func writeFile(path string, data []byte) (err error) {
    f, err := os.Create(path)
    if err != nil {
        return err
    }
    defer func() {
        closeErr := f.Close()
        if err == nil {
            err = closeErr
        }
    }()
    w := bufio.NewWriter(f)
    if _, err = w.Write(data); err != nil {
        return err
    }
    return w.Flush()
}
```

Pitfall #7 · Data Race on Map (fatal crash, not panic)

The Bug:

```
m := make(map[string]int)
go func() { m["a"] = 1 }()
go func() { m["b"] = 2 }()
// fatal error: concurrent map writes · PROCESS KILLED, cannot
recover()
```

Why it happens: Since Go 1.6, the runtime inserts a write flag check in map operations. If two goroutines write simultaneously, the runtime calls `throw()`, not `panic()`. This is an **unrecoverable fatal error** ·`recover()` cannot catch it.

```
  Goroutine 1: map write · sets hashWriting flag
  Goroutine 2: map write · sees hashWriting flag · throw("concurrent
map writes")
  ..........................................
  ·  FATAL: not a panic · cannot recover()   ·
  ·  Process exit code 2, stack trace dumped  ·
  ..........................................
```

How to detect: `go test -race ./...` · the race detector catches this before production.

How to fix: Use `sync.RWMutex` for general maps, or `sync.Map` for the two specific patterns it's optimized for (write-once-read-many, disjoint key sets per goroutine):

```
var mu sync.RWMutex
var m = make(map[string]int)
// Write
mu.Lock()
m["a"] = 1
mu.Unlock()
// Read
mu.RLock()
v := m["a"]
mu.RUnlock()
```

Pitfall #8 · Closure Capturing Loop Variable (pre-Go 1.22)

The Bug (Go < 1.22):

```
for _, v := range items {
    go func() {
        process(v)      // all goroutines see the LAST value of v
    }()
}
```

Why it happens: Before Go 1.22, the loop variable `v` was a single variable reused across all iterations. Closures capture the variable by reference, not by value. By the time goroutines execute, `v` holds the final iteration's value.

Status: Fixed in Go 1.22 · each iteration now gets a new variable. But legacy code and older Go versions still have this bug. The fix for older code:

```
for _, v := range items {
    v := v              // shadow with per-iteration copy
    go func() {
        process(v)      // correct · each goroutine has its own copy
    }()
}
```

Pitfall #9 · String Concatenation in Loops ($O(n^2)$ allocations)

The Bug:

```
var s string
for _, item := range items {
    s += item.Name + ","      // each += allocates a NEW string
}
```

Why it happens: Strings in Go are immutable `{pointer, length}` headers. Each `+=` allocates a new backing array, copies the old content + new content. For n items, this is $O(n^2)$ total bytes copied.

How to fix:

```
var b strings.Builder
for _, item := range items {
    b.WriteString(item.Name)
    b.WriteByte(',')
}
```

```
s := b.String()             // single allocation at the end
```

`strings.Builder` uses an internal `[]byte` that grows with amortized O(1) appends. Pre-allocate with `b.Grow(estimatedSize)` for hot paths.

Pitfall #10 · JSON Unmarshaling to `interface{}` (numbers become float64)

The Bug:

```
var data map[string]interface{}
json.Unmarshal([]byte(`{"id": 12345678901234}`), &data)
id := data["id"].(int)     // PANIC: interface conversion: float64,
not int
// Even if it doesn't panic, float64 loses precision for large
int64 values
```

Why it happens: The JSON spec has a single `number` type. Go's `encoding/json` decodes all numbers into `float64` when the target is `interface{}`, because `float64` can represent both integers and decimals. But `float64` only has 53 bits of mantissa · integers > 2^53 lose precision silently.

How to fix: Use `json.Decoder` with `UseNumber()`, or unmarshal into a concrete struct:

```
dec := json.NewDecoder(bytes.NewReader(raw))
dec.UseNumber()                                // numbers become
json.Number (string)
dec.Decode(&data)
id, _ := data["id"].(json.Number).Int64()        // safe conversion
```

Pitfall #11 · `context.Value` Abuse (dependency injection via context)

The Bug:

```
ctx = context.WithValue(ctx, "db", dbConn)
ctx = context.WithValue(ctx, "logger", logger)
ctx = context.WithValue(ctx, "userID", uid)
// deep in the call stack:
db := ctx.Value("db").(*sql.DB)     // type-unsafe, invisible
dependency, O(n) lookup
```

Why it happens: `context.WithValue` creates a linked list. Each `Value()` call walks the chain · O(n) in context depth. Worse, it hides dependencies: the function signature doesn't reveal what the function needs, making testing and refactoring dangerous.

```
ctx.Value("db") walks:
ctx4{key:"userID"} · ctx3{key:"logger"} · ctx2{key:"db"} · FOUND
     .                    .                    .
     O(1)                 O(2)                 O(3) · linear walk
```

Legitimate uses: request-scoped metadata that crosses API boundaries (trace ID, request ID, auth claims). NOT for services, connections, or config.

How to fix: Pass dependencies explicitly via constructor injection:

```
func NewHandler(db *sql.DB, logger *slog.Logger) *Handler {
    return &Handler{db: db, logger: logger}
```

```
}
```

Pitfall #12 · Unbounded Goroutine Spawning (no backpressure, OOM)

The Bug:

```
for _, job := range jobs {          // 1 million jobs
    go process(job)                 // 1 million goroutines · OOM
}
```

Why it happens: Each goroutine costs ~2-8 KB stack + heap objects it allocates. 1 million goroutines = 2-8 GB just in stacks, plus all their allocations. No backpressure means the system cannot push back when overwhelmed.

How to fix: Use a semaphore pattern or worker pool:

```
sem := make(chan struct{}, maxWorkers)
var wg sync.WaitGroup
for _, job := range jobs {
    sem <- struct{}{}               // blocks when maxWorkers
goroutines are running
    wg.Add(1)
    go func(j Job) {
        defer func() { <-sem; wg.Done() }()
        process(j)
    }(job)
}
wg.Wait()
```

Pitfall #13 · Silent Panic in Goroutine (crashes entire process)

The Bug:

```
go func() {
    result := riskyOperation()      // panics!
    ch <- result
}()
// panic in a goroutine is NOT caught by the caller's recover()
// the entire process crashes with a stack trace
```

Why it happens: `recover()` only works within the same goroutine's deferred function. A panic in a child goroutine propagates up to `runtime.main` and kills the entire process · even if the parent has `recover()`.

How to fix: Every goroutine you launch should have panic recovery:

```
go func() {
    defer func() {
        if r := recover(); r != nil {
            log.Printf("recovered panic: %v\n%s", r, debug.Stack())
        }
    }()
    result := riskyOperation()
    ch <- result
}()
```

For HTTP servers, `net/http` already recovers panics per-handler. For worker goroutines, you MUST add recovery yourself.

Pitfall #14 · Copying sync Types (Mutex, WaitGroup, Cond)

The Bug:

```
type Service struct {
    mu sync.Mutex
    cache map[string]string
}
func (s Service) Get(key string) string {   // VALUE receiver · copies s, copies mu!
    s.mu.Lock()
    defer s.mu.Unlock()
    return s.cache[key]                     // locking a COPY of the mutex · no protection
}
```

Why it happens: `sync.Mutex` contains internal state (wait queue, lock flag). Copying it creates a second mutex with duplicated state · the copy and original are independent. The `noCopy` sentinel embedded in sync types triggers `go vet` warnings.

How to detect: `go vet ./...` catches this: `copies lock value: sync.Mutex`.

How to fix: Use pointer receivers for any struct containing sync types:

```
func (s *Service) Get(key string) string {  // POINTER receiver · no copy
    s.mu.Lock()
    defer s.mu.Unlock()
    return s.cache[key]
}
```

Pitfall #15 · HTTP Handler Not Draining Request Body

The Bug:

```
func handler(w http.ResponseWriter, r *http.Request) {
    if r.ContentLength > maxSize {
        http.Error(w, "too large", 413)
        return                              // body not read · connection can't be reused!
    }
    // ...
}
```

Why it happens: HTTP/1.1 connection reuse (keep-alive) requires the full request body to be consumed. If the handler returns without reading the body, the server must close the connection · no reuse. Under load, this creates a flood of new TCP connections (with TLS handshake cost).

How to fix: Drain and close the body:

```
func handler(w http.ResponseWriter, r *http.Request) {
```

```
        defer func() {
            io.Copy(io.Discard, r.Body)
            r.Body.Close()
        }()
        if r.ContentLength > maxSize {
            http.Error(w, "too large", 413)
            return
        }
        // ...
    }
```

---

2. Library & Framework Comparison Tables

HTTP Routers

	net/http (stdlib)	**chi**	**gin**	**echo**
Description	stdlib router; Go 1.22 added `GET /users/{id}` pattern matching	Lightweight, idiomatic; 100% compatible with `net/http`	Full framework; fastest benchmarks; Radix tree router	Full framework; similar to Express.js in feel
Pros	Zero deps; always maintained; core team support	Stdlib compatible; middleware-first; small API surface	Fast; huge ecosystem; battle-tested at scale	Good docs; WebSocket/HTTP2 built-in; nice API
Cons	No middleware chaining stdlib; new patterns are basic	Smaller community than gin; fewer tutorials	Uses own `*gin.Context` · not stdlib `http.Handler`; heavy	Uses own `echo.Context`; smaller community
When to use	Simple services; when zero deps matters	Best default choice for most services	High-perf APIs; team already knows gin	Teams from Node/Express background
Who uses it	Everyone (stdlib)	Cloudflare, Heroku	Uber, many startups	Various
Maintenance	Go team (forever)	Active	Active	Active
Verdict	· Always safe	**Recommended default**	·· Good but not idiomatic	·· Good but not idiomatic

Logging

	log/slog (stdlib)	**zap (Uber)**	**zerolog**	**logrus**
Description	Structured logging in stdlib since Go 1.21; `slog.Logger` with handlers	Uber's zero-allocation structured logger	Zero-allocation JSON logger	Oldest structured logger; widely used
Pros	Stdlib; standard API; handler interface extensible	Fastest; zero-alloc hot path; battle-tested at Uber scale	Very fast; small API; zero-alloc	Familiar API; huge plugin ecosystem
Cons	Newer; fewer handlers available	Large API surface; Uber-specific patterns	Fluent API feels non-Go; less flexible	**Maintenance mode**; slower than zap/zerolog
When to use	New projects; when stdlib preference is strong	Latency-critical services needing maximum perf	When binary size and speed matter most	Legacy projects already using it
Who uses it	Go community (growing)	Uber, many large companies	Various	Docker, many older projects
Verdict	· Production-proven	**Recommended default**	· Good alternative	· Don't adopt new

Database

	database/sql	**sqlx**	**pgx**	**GORM**	**sqlc**
Description	Stdlib SQL interface; driver-agnostic	Extension of `database/sql`; struct scanning	PostgreSQL-native driver; no `database/sql` wrapper	Full ORM; auto-migrations; associations	Code gen from SQL queries · type-safe Go
Pros	Stable; driver-agnostic; well understood	Drop-in upgrade; named params; struct scan	Fastest PG driver; LISTEN/NOTIFY; COPY; batch	Rapid prototyping; migrations; associations	Compile-time SQL validation; no runtime reflection
Cons	Verbose; manual scanning; no named params	Still limited to `database/sql` perf	PostgreSQL only; non-standard API	Slow; magic; hard to debug; fights Go philosophy	Only SQL · Go (not Go · SQL); learning curve
When to use	Multi-DB support; simple queries	Upgrade path from `database/sql`	PostgreSQL services needing max performance	Prototypes; CRUD-heavy apps (controversial)	Services with complex queries; type safety
Who uses it	Everyone	Many companies	Many PG-heavy services	Startups, rapid dev	Stripe, many Go teams
Verdict	· Safe baseline	· Easy upgrade	**Best for PostgreSQL**	·· Controversial	**Recommended for SQL-heavy**

Configuration

| | **os.Getenv + flags** | **viper** | **envconfig** | **koanf** | |---|---|---|---|---| | **Description** | Stdlib env vars + `flag` package | Full config solution: files, env, remote, flags | Struct tags · env vars mapping | Modular config library; provider-based | | **Pros** | Zero deps; simple; explicit | Everything included; popular; multi-format | Dead simple; zero magic; one job done well | Clean API; composable providers; no globals | | **Cons** | No file parsing; no struct mapping; manual | Heavy; global state; too much magic; slow | Only env vars; no file support | Less popular; newer | | **When to use** | Simple services; 12-factor apps | Legacy; complex config sources | 12-factor microservices | Modern replacement for viper | | **Verdict** | · Start here | ·· Overused | · Good for microservices | · Modern choice |

Testing

| | **testing (stdlib)** | **testify** | **go-cmp (Google)** | **gomock / mockgen** | |---|---|---|---|---| | **Description** | Built-in test framework; `go test` | Assertions, require, suite, mock | Deep equality comparison with diff output | Interface mock generation | | **Pros** | Always available; table-driven tests; subtests; fuzzing | Familiar assertions; reduces boilerplate; wide adoption | Semantic comparison; diff output; option composability | Auto-generates mocks; strict expectations | | **Cons** | Verbose assertions (`if got != want`); no diff | Extra dep; `suite` promotes non-Go patterns; controversial | Only comparison, not full assertion library | Generated code is verbose; tight coupling to impl | | **When to use** | Always · is the foundation | When team prefers assertion style | Complex struct comparison; golden file tests | When you need strict call verification | | **Verdict** | · **Always use** | ·· Divisive in community | · **Recommended for comparisons** | ·· Use sparingly |

CLI Frameworks

| | **cobra + pflag** | **urfave/cli** | |---|---|---| | **Description** | Command-based CLI framework; used by kubectl, hugo, gh | Simpler CLI framework; flag-centric | | **Pros** | Subcommands; completions; man pages; code gen; massive adoption | Simpler API; less boilerplate for small CLIs | | **Cons** | Heavy for simple tools; code gen creates noise | Less powerful; fewer features | | **When to use** | Any CLI with subcommands | Simple single-command tools | | **Verdict** | · **Industry standard** | · Good for small tools |

Observability

| | **OpenTelemetry** | **prometheus/client_golang** | **Datadog / vendor SDKs** | |---|---|---|---| | **Description** | Vendor-neutral traces, metrics, logs SDK | Prometheus metrics client; exposition format | Vendor-specific telemetry SDKs | | **Pros** | Vendor-agnostic; CNCF standard; traces + metrics + logs | Simple; proven; huge ecosystem; pull-based | Turnkey; vendor support; advanced features | | **Cons** | Large API surface; still maturing; complexity | Metrics only; no traces; push requires adapter | Vendor lock-in; cost | | **When to use** | New services; when vendor flexibility matters | Prometheus/Grafana stack; Kubernetes native | When vendor is already chosen and paid for | | **Verdict** | · **Future standard** | · Proven for metrics | ·· Pragmatic but locked in |

Dependency Injection

| | **Manual (main wiring)** | **wire (Google)** | **fx (Uber)** | **dig (Uber)** | |---|---|---|---|---| | **Description** | Explicit constructor calls in `main()` | Compile-time DI via code generation | Runtime DI container; lifecycle management | Runtime DI container (fx is built on dig) | | **Pros** | Explicit; debuggable; no magic; Go-idiomatic | Compile-time errors; no runtime overhead | Lifecycle hooks; module system; good for large apps | Simpler than fx; just dependency resolution | | **Cons** | Verbose `main()` for large apps; manual ordering | Code gen step; limited adoption; learning curve | Runtime errors; magic; opaque; hard to debug | Runtime errors; reflection-based | | **When to use** | Most services (up to ~30 dependencies) | Large services where manual wiring is painful | Very large services with complex lifecycle | When you want dig without fx's lifecycle | | **Verdict** | · **Recommended default** | · Good for large apps | ·· Uber-style only | ·· Uber-style only |

---

3. The Go Community's Strong Opinions

These aren't just conventions · they're battle-tested principles with real production reasoning behind each one.

The Opinions, Ranked by Consensus Strength

##	Opinion	Why
1	go test -race in CI is non-negotiable	Data races are UNRECOVERABLE fatals in Go. Race detector has ~zero false positives. Cost: 5-10x slowdown · worth it.
2	Accept interfaces, return concrete types	Interfaces in params = flexible, testable. Concrete returns = discoverable, no alloc. Consumer defines the interface, not provider.
3	Context as first parameter (ctx context.Context)	Convention enforced by go vet. Enables cancellation, timeouts, tracing propagation. Never store context in a struct.
4	Prefer stdlib when possible	"A little copying is better than a little dependency." Fewer transitive deps = fewer supply chain attacks, faster builds.
5	Small interfaces (1-3 methods)	"The bigger the interface, the weaker the abstraction." io.Reader (1 method) is the most composed interface in the stdlib.
6	Table-driven tests	Reduces test boilerplate; easy to add cases; subtests enable t.Parallel() and -run filter. The Go standard, used throughout stdlib.
7	Structured logging with slog	JSON logs are machine-parseable. slog is now stdlib (Go 1.21+). No

```

```

The Interface Location Rule

This deserves special attention because it's counter-intuitive for Java/C# developers:

```
  · Java/C# style: interface defined by the PROVIDER (the package
that implements it)
  ····· provider/repo.go ·····     ····· consumer/service.go ·····
  · type UserRepo interface { ·     · import "provider"            ·
  ·   Get(id int) (*User, err)·     ·                              ·
  ·   Save(u *User) error     ····· func NewService(              ·
  · }                         ·     ·   repo provider.UserRepo,    ·
  · type PGRepo struct{...}   ·     · ) *Service                   ·
  · func (p *PGRepo) Get(...) ·     ·                              ·
  ............................     ................................
  Consumer depends on provider package · tight coupling!
  · Go style: interface defined by the CONSUMER (the package that
uses it)
  ····· repo/pg.go ···........     ····· service/service.go ·......
  · type PGRepo struct{...}  ·     · type UserStore interface {    ·
  · func (p *PGRepo) Get(...)|     ·   Get(id int) (*User, error)  ·
  · func (p *PGRepo) Save(..)|     · }                              ·
  ............................     · func NewService(              ·
          ·                         ·   store UserStore,            ·
          · satisfies implicitly    · ) *Service                    ·
          ........................                                  ·
                                    ................................
  Consumer defines only the methods IT needs · decoupled!
```

4. Project Structure for Enterprise

The Standard Layout

```
myservice/
··· cmd/                          # Entry points · one main package
per binary
·   ··· api-server/
·   ·   ··· main.go                # Wires dependencies, starts HTTP
server
·   ··· worker/
·       ··· main.go                # Wires dependencies, starts job
consumer
·
··· internal/                     # Private packages ·
compiler-enforced boundary
·   ··· domain/                    # Business entities + repository
interfaces
·   ·   ··· user.go                # type User struct; type UserStore
interface
·   ·   ··· order.go               # type Order struct; type OrderStore
interface
·   ·
·   ··· service/                   # Business logic · orchestrates
domain
·   ·   ··· user_service.go        # func NewUserService(store
domain.UserStore)
·   ·   ··· order_service.go
·   ·
·   ··· repository/                # Data access · implements domain
interfaces
·   ·   ··· postgres/
·   ·   ·   ··· user_repo.go       # type PGUserRepo struct; implements
domain.UserStore
·   ·   ·   ··· order_repo.go
·   ·   ··· redis/
·   ·       ··· cache.go
·   ·
·   ··· handler/                   # HTTP/gRPC transport · depends on
service
·   ·   ··· user_handler.go        # Routes, request parsing, response
writing
·   ·   ··· middleware.go          # Logging, auth, recovery middleware
·   ·   ··· router.go             # Assembles routes + middleware
·   ·
·   ··· platform/                  # Cross-cutting concerns
·       ··· config/                # Config loading + validation
·       ··· logging/               # slog setup + middleware
·       ··· metrics/               # Prometheus/OTel registration
·       ··· database/             # Connection pool setup
·
```

```
··· pkg/                            # Public reusable packages (use
sparingly!)
·   ··· httputil/                    # Shared HTTP helpers (only if
truly reusable)
·
··· api/                            # API definitions
·   ··· openapi.yaml                # REST API spec
·   ··· proto/                      # gRPC protobuf definitions
·       ··· user/v1/user.proto
·
··· migrations/                     # Database migrations (goose,
golang-migrate)
·   ··· 001_create_users.up.sql
·   ··· 001_create_users.down.sql
·
··· deployments/                    # Infrastructure
·   ··· Dockerfile
·   ··· docker-compose.yml
·   ··· k8s/
·       ··· deployment.yaml
·       ··· service.yaml
·
··· go.mod
··· go.sum
··· Makefile
```

The Dependency Rule

Dependencies flow inward · outer layers depend on inner layers, never the reverse:

```
  ..............................................................
  ·                       cmd/main.go                          ·
  ·                    (composition root)                       ·
  ·  Wires everything: repo · service · handler · http.Server  ·
  ..............................................................
                .              .              .
                .              .              .
  ................  ................  ................
  ·   handler/   ·  ·   service/   ·  ·  repository/ ·
  ·  depends on  ····  depends on  ····  implements  ·
  ·  service     ·  ·  domain      ·  ·  domain      ·
  ................  ................  ................
                          .                 .
                          .                 .
                    ...............................
                    ·          domain/            ·
                    ·  entities + interfaces      ·
                    ·  DEPENDS ON NOTHING         ·
                    ...............................
  Key rules:
  ·· domain/ imports NOTHING from internal/ (no circular deps)
  ·· service/ imports domain/ only (never handler/ or repository/)
  ·· repository/ imports domain/ (implements its interfaces)
  ·· handler/ imports service/ (calls business logic)
```

```
  ·· cmd/main.go imports everything (the composition root)
```

Why `internal/` Matters

The `internal/` directory is **compiler-enforced** · only the parent module can import packages under `internal/`. This means:

```
  myservice/internal/domain/user.go  · importable by
myservice/cmd/api-server
  myservice/internal/domain/user.go  · NOT importable by ANY other
module
  This is Go's answer to "package-private" in Java.
  No keyword needed · just directory placement.
```

---

5. Graceful Shutdown · The Production Pattern

Order matters. Get this wrong and you lose in-flight requests or corrupt data.

```
  Signal received (SIGTERM/SIGINT)
  ·
  ·· 1. Stop accepting new connections
  ·     ·· http.Server.Shutdown(ctx) · stops listener, waits for
in-flight
  ·
  ·· 2. Drain in-flight requests
  ·     ·· Shutdown waits until all active handlers return (or ctx
deadline)
  ·
  ·· 3. Stop background workers
  ·     ·· Cancel worker context · workers finish current job · exit
  ·
  ·· 4. Close external connections
  ·     ·· Database pools, Redis, message queues · close in reverse init
order
  ·
  ·· 5. Flush buffers
  ·     ·· Flush logs, metrics, trace spans
  ·
  ·· 6. Exit
        ·· os.Exit(0) · clean shutdown
```

The Complete Implementation

```
func main() {
    // ·· Setup ······························································
    cfg := config.MustLoad()
    logger := slog.New(slog.NewJSONHandler(os.Stdout, nil))
    db, err := sql.Open("pgx", cfg.DatabaseURL)
    if err != nil {
        logger.Error("failed to connect to database", "error", err)
        os.Exit(1)
    }
```

```
    svc := service.NewUserService(repository.NewPGUserRepo(db))
    handler := handler.NewRouter(svc, logger)
    srv := &http.Server{
        Addr:         cfg.Addr,
        Handler:      handler,
        ReadTimeout:  5 * time.Second,
        WriteTimeout: 10 * time.Second,
        IdleTimeout:  120 * time.Second,
    }
    // ·· Start server in background ······################################
    go func() {
        logger.Info("server starting", "addr", cfg.Addr)
        if err := srv.ListenAndServe(); err != nil && err !=
http.ErrServerClosed {
            logger.Error("server error", "error", err)
            os.Exit(1)
        }
    }()
    // ·· Wait for shutdown signal ······################################
    ctx, stop := signal.NotifyContext(context.Background(),
syscall.SIGINT, syscall.SIGTERM)
    defer stop()
    <-ctx.Done()
    logger.Info("shutdown signal received, draining...")
    // ·· Graceful shutdown sequence ······################################
    shutdownCtx, cancel :=
context.WithTimeout(context.Background(), 30*time.Second)
    defer cancel()
    // 1. Stop accepting new connections + drain in-flight requests
    if err := srv.Shutdown(shutdownCtx); err != nil {
        logger.Error("server shutdown error", "error", err)
    }
    // 2. Close database connections
    if err := db.Close(); err != nil {
        logger.Error("database close error", "error", err)
    }
    logger.Info("shutdown complete")
}
```

Key Details

Concern	Setting	Why
`ReadTimeout`	5s	Prevent slowloris attacks
`WriteTimeout`	10s	Bound total response time
`IdleTimeout`	120s	Reuse connections but don't hold forever
Shutdown timeout	30s	Kubernetes sends SIGKILL after `terminationGracePeriodSeconds` (default 30s)
`http.ErrServerClosed`	Check in ListenAndServe error	Normal during shutdown · not an error

---

6. Docker Multi-Stage Build · The Standard

The Dockerfile

```
# ·· Stage 1: Build ······##########################################
```

```
FROM golang:1.23-alpine AS builder
WORKDIR /app
# Cache dependency downloads
COPY go.mod go.sum ./
RUN go mod download
# Build with all optimizations
COPY . .
RUN CGO_ENABLED=0 GOOS=linux GOARCH=amd64 \
    go build -ldflags="-s -w" -o /app/server ./cmd/api-server
# ·· Stage 2: Runtime ··················································
FROM gcr.io/distroless/static-debian12:nonroot
COPY --from=builder /app/server /server
# Container-aware runtime settings
ENV GOMEMLIMIT=450MiB
ENV GOMAXPROCS=2
EXPOSE 8080
ENTRYPOINT ["/server"]
```

Build Flags Explained

```
CGO_ENABLED=0        · Pure Go binary, no C dependencies, works on
scratch/distroless
GOOS=linux           · Cross-compile target OS
GOARCH=amd64         · Target architecture (arm64 for
Graviton/M-series)
-ldflags="-s -w"     · Strip debug symbols and DWARF info (~30%
smaller binary)
```

Container Runtime Settings

```
·····————————————————————————————————————————————————————————————————
· GOMEMLIMIT (Go 1.19+)
    ·
·
     ·
· Sets a soft memory limit for the Go runtime. GC runs more
aggressively   ·
· as heap approaches this limit. Set to ~90% of container memory
limit.    ·
·
     ·
·   Container limit: 512 MiB · GOMEMLIMIT=450MiB
  ·
·   Container limit: 1 GiB   · GOMEMLIMIT=900MiB
  ·
·
     ·
· Without this, Go has no idea it's in a container and may OOM.
     ·
·————————————————————————————————————————————————————————————————————
· GOMAXPROCS
     ·
·
```

```
     .
· Number of OS threads for goroutine scheduling. Defaults to all host
CPUs ·
· · in a container, this sees HOST CPUs, not the cgroup limit!
     .
·
     .
· Fix: use uber-go/automaxprocs (reads cgroup CPU limit at startup):
     .
·   import _ "go.uber.org/automaxprocs"
     .
·
     .
· Or set manually: GOMAXPROCS=2 for a 2-CPU container.
     .
.........................................................................
· Health Check Endpoints
     .
·
     .
·   /healthz  (liveness)  · "am I alive?" · restart if unhealthy
 .
·   /readyz   (readiness) · "can I serve?" · remove from load balancer
 .
·
     .
·   Readiness should check: DB connection, cache connection, config
loaded ·
·   Liveness should be cheap: return 200 OK (don't check
dependencies)     ·
.........................................................................
```

Image Size Comparison

| Base Image | Size | Security | Use When | |---|---|---|---| | `golang:1.23` | ~800 MB | Full OS, many CVEs | Never for production | | `alpine:3.19` | ~7 MB + binary | Minimal, musl libc | Need shell for debugging | | `distroless/static` | ~2 MB + binary | No shell, no package manager | **Recommended default** | | `scratch` | 0 MB + binary | Nothing at all | When you handle TLS certs yourself |

---

7. Middleware Pattern · The Go Way

The Signature

```go
// The universal Go middleware signature
type Middleware func(next http.Handler) http.Handler
```

This creates a chain where each middleware wraps the next handler:

```
  Request
Response
  .......  ...........  ...........  ...........  ........  .......
           · Logging  ···· Auth    ···· Rate    ···· Your  ·
```

```
            · MW       ·  · MW      ·  · Limit   ·  ·Handler·
  .......  ...........  ...........  ...........  ........  .......
  Response
Request
  (unwinding)
  Execution order:
  1. Logging MW (before) · 2. Auth MW (before) · 3. Rate Limit (before)
  · 4. Handler · 3. Rate Limit (after) · 2. Auth MW (after) · 1. Logging
(after)
```

Standard Middleware Implementations

Recovery Middleware · catches panics, returns 500:

```
func Recovery(logger *slog.Logger) Middleware {
    return func(next http.Handler) http.Handler {
        return http.HandlerFunc(func(w http.ResponseWriter, r
*http.Request) {
            defer func() {
                if err := recover(); err != nil {
                    logger.Error("panic recovered",
                        "error", err,
                        "stack", string(debug.Stack()),
                        "path", r.URL.Path,
                    )
                    http.Error(w, "Internal Server Error", 500)
                }
            }()
            next.ServeHTTP(w, r)
        })
    }
}
```

Request ID Middleware · adds trace correlation:

```
func RequestID(next http.Handler) http.Handler {
    return http.HandlerFunc(func(w http.ResponseWriter, r
*http.Request) {
        id := r.Header.Get("X-Request-ID")
        if id == "" {
            id = uuid.NewString()
        }
        ctx := context.WithValue(r.Context(), requestIDKey, id)
        w.Header().Set("X-Request-ID", id)
        next.ServeHTTP(w, r.WithContext(ctx))
    })
}
```

Timeout Middleware · enforces handler deadline:

```
func Timeout(d time.Duration) Middleware {
    return func(next http.Handler) http.Handler {
        return http.TimeoutHandler(next, d, "request timeout")
    }
}
```

Composing Middleware

```
func Chain(middlewares ...Middleware) Middleware {
    return func(final http.Handler) http.Handler {
        for i := len(middlewares) - 1; i >= 0; i-- {
            final = middlewares[i](final)
        }
        return final
    }
}
// Usage:
stack := Chain(
    Recovery(logger),
    RequestID,
    Logging(logger),
    Timeout(30 * time.Second),
    Auth(tokenValidator),
    RateLimit(100),          // 100 req/sec
)
mux := http.NewServeMux()
mux.Handle("GET /users/{id}", stack(userHandler))
```

---

8. Configuration Management

The 12-Factor Approach

```
.......................................................................
·                     Configuration Hierarchy
 .
·                     (highest priority wins)
 .
·
 .
·  Priority 1: Environment variables        · secrets, per-env
overrides·
·  Priority 2: Config file (YAML/JSON/TOML) · non-sensitive defaults
·
·  Priority 3: Struct field defaults         · sane fallbacks
·
·
 .
·  Rule: NEVER commit secrets to code or config files.
 .
·  Rule: Config should be validated at startup, not at first use.
 .
.......................................................................
```

The Config Struct Pattern

```
type Config struct {
```

```
    Addr         string        `env:"ADDR"
default:":8080"`
    DatabaseURL  string        `env:"DATABASE_URL"
required:"true"`
    ReadTimeout  time.Duration `env:"READ_TIMEOUT"  default:"5s"`
    WriteTimeout time.Duration `env:"WRITE_TIMEOUT" default:"10s"`
    LogLevel     string        `env:"LOG_LEVEL"     default:"info"`
    MaxWorkers   int           `env:"MAX_WORKERS"   default:"10"`
}
func MustLoad() Config {
    var cfg Config
    if err := envconfig.Process("", &cfg); err != nil {
        log.Fatalf("config: %v", err)           // fail FAST at
startup
    }
    if err := cfg.Validate(); err != nil {
        log.Fatalf("config validation: %v", err)
    }
    return cfg
}
func (c Config) Validate() error {
    if c.MaxWorkers < 1 || c.MaxWorkers > 1000 {
        return fmt.Errorf("max_workers must be 1-1000, got %d",
c.MaxWorkers)
    }
    if c.ReadTimeout <= 0 {
        return fmt.Errorf("read_timeout must be positive")
    }
    return nil
}
```

Feature Flags · Simple Pattern

```
type FeatureFlags struct {
    EnableNewCheckout bool `env:"FF_NEW_CHECKOUT" default:"false"`
    EnableBetaAPI     bool `env:"FF_BETA_API"     default:"false"`
    MaxBatchSize      int  `env:"FF_MAX_BATCH"    default:"100"`
}
// In handler:
if cfg.Features.EnableNewCheckout {
    return newCheckoutHandler(w, r)
}
return legacyCheckoutHandler(w, r)
```

For production feature flag systems at scale, use a dedicated service (LaunchDarkly, Unleash, Flipt) that supports gradual rollouts, user targeting, and kill switches without redeployment.

Hot Reload with `atomic.Value`

```
var globalCfg atomic.Value  // stores *Config
func init() {
    globalCfg.Store(MustLoad())
}
```

```
func ReloadConfig() error {
    newCfg, err := Load()
    if err != nil {
        return fmt.Errorf("reload: %w", err)
    }
    globalCfg.Store(newCfg)         // atomic swap · no lock needed
for readers
    return nil
}
func GetConfig() *Config {
    return globalCfg.Load().(*Config)   // lock-free read
}
```

Caveat: Hot reload works for feature flags and tuning parameters. Do NOT hot-reload database URLs or listen addresses · those require a restart.

---

9. Quick Reference Card

Before You Ship to Production · Checklist

```
.......................................................................
·                    PRODUCTION READINESS CHECKLIST
  .
.......................................................................
·
 .
·  BUILD & TEST
 .
·  · go test -race ./...              Race detector in CI (ALWAYS)
·
·  · go vet ./...                      Static analysis
·
·  · golangci-lint run                 Comprehensive linting
·
·  · go test -count=1 ./...            No cached test results in CI
·
·  · go test -cover ./...              Know your coverage (don't fake)
·
·
 .
·  RUNTIME CONFIGURATION
 .
·  · GOMEMLIMIT set                   ~90% of container memory limit
·
·  · GOMAXPROCS set or automaxprocs   Match container CPU limit
·
·  · Config validated at startup      Fail fast, not on first request
·
·
 .
·  RESILIENCE
 .
```

· Graceful shutdown implemented	SIGTERM · drain · close · exit
· Panic recovery middleware	Every goroutine, every handler
· Context propagation	Timeouts and cancellation chain
· HTTP client timeouts set	Never use http.DefaultClient
· Database connection pool sized	SetMaxOpenConns, SetMaxIdleConns
· Retry with backoff	Exponential backoff on transient

OBSERVABILITY

· Structured logging (slog/zap)	JSON format, request-scoped
· Metrics exported	RED: Rate, Errors, Duration
· Health endpoints	/healthz (live), /readyz (ready)
· pprof enabled (behind auth)	/debug/pprof/* for production
· Request IDs propagated	Correlation across services

SECURITY

· TLS configured (MinVersion 1.2)	crypto/tls with sane defaults
· Input validated at boundary	Never trust user input
· SQL parameterized	$1, $2 · never string concat
· Secrets in env vars / vault	Never in code or config files
· Distroless/scratch Docker image	Minimal attack surface
· Rate limiting enabled	Per-client, per-endpoint

GOROUTINE HYGIENE

· No unbounded goroutine spawning	Use semaphore / worker pool
· Every goroutine has exit path	Context cancellation or signal
· uber-go/goleak in tests	Detects goroutine leaks
· No sync type copying	go vet catches this

```
·  PERFORMANCE BASELINE
 ·
·  · Benchmarks for hot paths         go test -bench=. -benchmem
·
·  · Escape analysis reviewed         go build -gcflags='-m' on hot
·
·  · Slices/maps pre-allocated        Reduce GC pressure
·
·  · sync.Pool for high-churn objects Buffers, temporary structs
·
·
 ·
·  DEPLOYMENT
 ·
·  · Multi-stage Docker build         Builder · distroless/scratch     ·
·  · Kubernetes probes configured     livenessProbe + readinessProbe
·
·  · terminationGracePeriodSeconds    Match your shutdown timeout
·
·  · Resource limits set              CPU + memory limits in k8s
·
·
 ·
.......................................................................
```

Quick Debugging Commands

```
# Goroutine dump (find leaks)
curl http://localhost:6060/debug/pprof/goroutine?debug=2
# CPU profile (30 seconds)
go tool pprof http://localhost:6060/debug/pprof/profile?seconds=30
# Heap profile (current allocations)
go tool pprof http://localhost:6060/debug/pprof/heap
# GC trace (see GC pauses and frequency)
GODEBUG=gctrace=1 ./myservice
# Scheduler trace (see goroutine scheduling)
GODEBUG=schedtrace=1000 ./myservice
# Execution trace (visual timeline)
curl -o trace.out http://localhost:6060/debug/pprof/trace?seconds=5
go tool trace trace.out
# Race detector (in tests)
go test -race -count=1 ./...
# Escape analysis (what allocates on heap)
go build -gcflags='-m -m' ./... 2>&1 | grep 'escapes to heap'
```

The "Never Do This" List

```
.......................................................................
·  · NEVER use http.DefaultClient in production                       ·
·     · No timeouts. A hanging server blocks your goroutine forever.
·
·     · Create: &http.Client{Timeout: 10 * time.Second}               ·
·
```

```
 .
·   · NEVER use http.ListenAndServe(addr, handler) directly            ·
·      · No timeouts, no graceful shutdown.
·
·      · Create: &http.Server{...} with all timeouts set.              ·
·
 .
·   · NEVER log errors at every layer                                  ·
·      · Log ONCE at the top (handler). Wrap with context at each
layer.·
·      · return fmt.Errorf("repo.GetUser: %w", err) · don't log here.  ·
·
 .
·   · NEVER use init() for complex setup                               ·
·      · init() runs at import time, before main(). Hard to test.
·
·      · Put setup in main() or constructors.
·
·
 .
·   · NEVER store context.Context in a struct field
·
·      · Context is request-scoped. Struct fields outlive requests.
·
·      · Pass ctx as the first parameter to methods.
·
·
 .
·   · NEVER use panic for expected error conditions
·
·      · Panic is for programmer errors (bug in the code).
·
·      · Return errors for operational failures (network, disk, input).
·
·
 .
·   · NEVER ignore the error from rows.Close() or resp.Body.Close()    ·
·      · Wrap in a helper or use named returns to capture.
·
·
 .
·   · NEVER launch a goroutine without knowing how it stops            ·
·      · Every go func() needs a cancellation path (context, channel,
·
·        or done signal).
 .
.......................................................................
```

Go Proverb: *"Don't just check errors, handle them gracefully."*
Production Go isn't about writing clever code · it's about writing code that fails predictably, recovers gracefully, and is debuggable at 3 AM with only `pprof` and structured logs. Every pattern in this document exists because someone learned it the hard way.
